

Title: A proposed Test of the Local Causality of Spacetime

Date: Jul 21, 2006 10:15 AM

URL: <http://pirsa.org/06070057>

Abstract: A theory governing the metric and matter fields in spacetime is {\it locally causal} if the probability distribution for the fields in any region is determined solely by physical data in its past, i.e. it is independent of events at space-like separated points. This is the case according to general relativity, and it is natural to hypothesise that it should also hold true in any theory in which the fundamental description of space-time is classical and geometric --- for instance, some hypothetical theory which stochastically couples a classical spacetime geometry to a quantum field theory of matter. On the other hand, a quantum theory of gravity should allow the creation of spacetimes which macroscopically violate local causality.

I describe a feasible experiment to test the local causality of spacetime, and hence to test whether gravity is better described, in this respect, by general relativity or by quantum theory. The experiment will either identify a definite limit to the domain of validity of quantum theory or else produce significant evidence for the hypothesis that gravity is described by a quantum theory.

Is spacetime causally or spacelike?

A. an Kent

Talk @ Shimony-fest @ PI

1015.21.07.2006

I want to argue that it's both meaningful
and interesting, theoretically, to ask whether the
gravitational field is locally causal (using a
definition generalising Bell's). I also want to
discuss experimental tests, including a beautiful
recent proposal of Gisin et al., that can
address and ^{eventually} definitively resolve the question.

(A.I.C. quant-ph/0507045; also 0204104)

Some working assumptions

- ① We just don't understand how to unify quantum theory and gravity; we don't even know whether any of the currently fashionable programmes are on the right track. That doesn't stop us from having strong hunches about how things must work, but it makes it important to verify them if there's room for a sliver of doubt.
- ② The measurement problem makes it reasonable to suppose that quantum theory is augmented by some mathematical account of "localised beables" or "real events" — possibly associated with localised collapses of the wave function.
- ③ At least at mesoscopic scales, gravity is described by a spacetime metric $g_{\mu\nu}$, whose geodesics determine trajectories for test masses. Moreover, the metric is a real quantity, in the sense of ② above: either it is a fundamental beable or it's effectively determined by them.

Some working assumptions

What would happen in the ideal experiment?

Standard intuition (I think): The Bell-CHSH experiment produces nonlocal relations. These are faithfully translated to the distributions of matter lumps on each wing, and hence to the corresponding measured gravitational fields.

IF SO, we have direct experimental evidence for the gravitational field violating local causality (contradicting the geometric intuition inspired by general relativity).

A logically possible alternative: When we couple a Bell-CHSH experiment to gravitational fields as described, we find that the nonlocal correlations predicted by q.m. are NOT observed.

IF SO — obviously it would be a huge surprise — we would have evidence that the gravitational field respects local causality, in accord with general relativistic intuition but in dramatic contradiction with quantum theory.

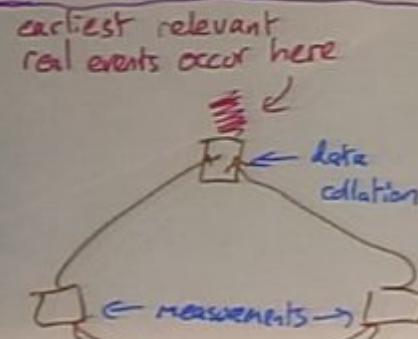

(There are even stranger logical possibilities — for example the matter lumps' positions could be nonlocally correlated but the associated gravitational fields could not be: this would mean violating Newtonian gravity until a signal could reach from one wing to the other.
But I'll neglect these here.)

Is the experiment worth doing?

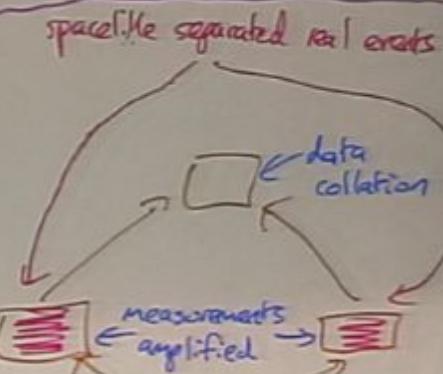

"Logically possible" doesn't really cut much ice as a motivation: lots o' silly hypotheses are logically possible. What, if anything, makes this proposal better motivated? I would offer two reasons (but maybe there are others).

① already mentioned - the tension between intuitions from g.r. and q.m. (One might imagine, for example, some hybrid theory of classical metric and quantum matter, in which the probability distribution for classical spacetimes is — axiomatically — required to satisfy local causality.)

② The possibility that, quite generally, spacelike separated beables or "real events" do not have nonlocal correlations
⇒ in particular the space-time metric, being real, obeys local causality.

⇒ in particular the space-time metric, being real, obeys local causality.

Is the experiment worth doing?

"Logically possible" doesn't really cut much ice as a motivation; lots of silly hypotheses are logically possible. What, if anything, makes this proposal better motivated? I would offer two reasons (but maybe there are others).

- ① already mentioned - the tension between intuitions from g.r. and q.m. (One might imagine, for example, some hybrid theory of classical metric and quantum matter, in which the probability distribution for classical spacetimes is — axiomatically — required to satisfy local causality.)
- ② The possibility that, quite generally, spacelike separated beables or "real events" do not have nonlocal correlations
⇒ in particular the space-time metric, being real, obeys local causality.

APPARENT BUT FAUX
NON-LOCAL CORRELATIONS

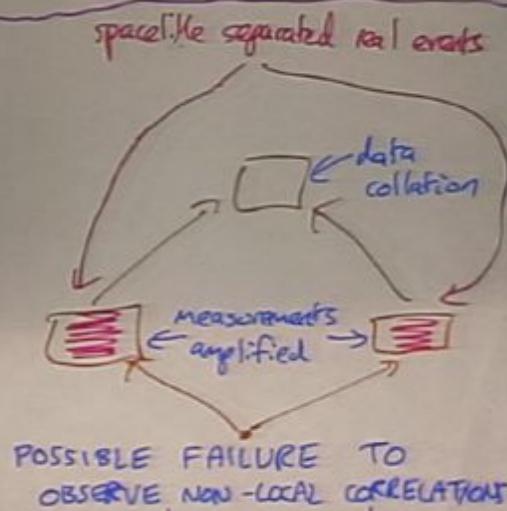

POSSIBLE FAILURE TO
OBSERVE NON-LOCAL CORRELATIONS

Possibility ② : the "collapse locality loophole" in Bell experiments to date

Spacelike separated collapse events (e.g. suitably amplified measurements) do not influence one another and \therefore do not display non-local correlations

Assuming some model of localised collapse, can define a consistent (if weird) alternative to standard quantum theory which has this property and which agrees with quantum theory for Bell experiments in which the collapses are not spacelike separated.

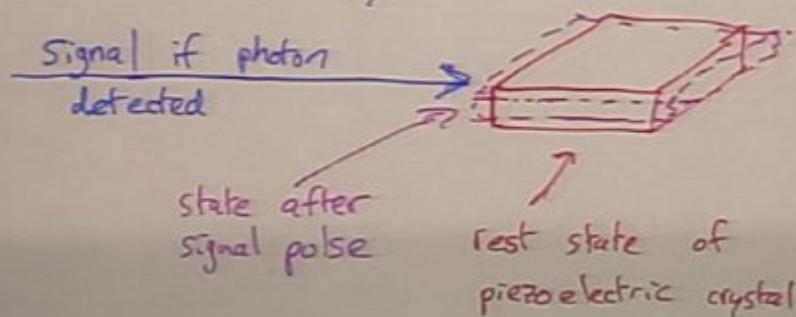

(cf A.M. Phys. Rev A 72 012107 (2005)
(q-ph/0204104))

Is (some interesting version of) the experiment feasible?

The ideal version may be difficult: even a 100nm separation in the \sim 1 experiment allows only 3×10^{-4} sec to create and measure macroscopically distinct gravitational fields.

However, Gisin et al. have a beautiful idea for a simpler version, which quickly creates (but doesn't directly measure) distinct gravitational fields

(ON EACH WING)

.... corresponding to two possible states of a piezoelectric crystal.

This hopefully should allow tests of the essential idea, for at least some plausible intuitions about gravity-related collapse.

Summary

- * There is a well-defined notion of local causality for metric space-time theories, extending Bell's definition for theories of events in Minkowski space.
- * In principle it is an open question whether gravity is described by a locally causal theory or not (though the standard intuition suggests not). And there is at least a sliver of motivation for considering the possibility that gravity is locally causal.
- * The question can be resolved by experiment, and some interesting (if not definitive) experiments in this direction appear presently feasible.
