

Title: Perfect function transfer in two and three dimensions without initialization

Date: Dec 13, 2010 04:00 PM

URL: <http://pirsa.org/10120044>

Abstract: We find analytic models that can perfectly transfer, without state initialization or remote collaboration, arbitrary functions in two- and three-dimensional interacting bosonic and fermionic networks. This provides for the possible experimental implementation of state transfer through bosonic or fermionic atoms trapped in optical lattices. A significant finding is that the state of a spin qubit can be perfectly transferred through a fermionic system. Families of Hamiltonians are described that are related to the linear models and that enable the perfect transfer of arbitrary functions. Furthermore, we propose methods for eliminating certain types of errors

Exact state transmissions exist universally, but not all of them are significant for state transfer.

Ideally, if an eigenstate is localized at processor A, that state can be transferred perfectly and can be used as **a basis** if known

QIP needs to transfer unknown state, which requires at least two **bases, e.g.,**

## Theorem (Wu et al. PRA80,042315 (2009)):

Assume that the entire system, processors A, B and the media (connecting A & B), is initially in a state

## Theorem (Wu et al. PRA80,042315 (2009):

Assume that the entire system, processors A, B and the media (connecting A & B), is initially in a state  $|\Phi(0)\rangle$

There exists a complete orthogonal set  $\{|\Phi_k(0)\rangle\}_\tau$  depending on  $\tau$ , such that an exact state transmission occurs if the initial state is one of the states in this set.

$|\Phi_k(0)\rangle_\tau$  are eigenstates of u-operators  $G(\tau) = P_{AB}U(\tau)$  -product of A-B exchange operator and evolution operator.

The eigenequation is

$$G(\tau) \left| \Phi_k(0) \right\rangle_{\tau} = \exp(i\phi_k) \left| \Phi_k(0) \right\rangle_{\tau}$$

Exact state transmissions exist universally, but not all of them are significant for state transfer.

Ideally, if an eigenstate is localized at processor A, that state can be transferred perfectly and can be used as **a basis** if known

QIP needs to transfer unknown state, which requires at least two **bases, e.g.,**

$$|\Phi_1(0)\rangle \text{ and } |\Phi_2(0)\rangle$$

Such that  $|\Phi(0)\rangle = a|\Phi_1(0)\rangle + b|\Phi_2(0)\rangle$  is also an eigenstate of  $G(\tau)$ .

$$|\Phi_1(0)\rangle \text{ and } |\Phi_2(0)\rangle$$

Such that  $|\Phi(0)\rangle = a|\Phi_1(0)\rangle + b|\Phi_2(0)\rangle$  is also an eigenstate of  $G(\tau)$ .

Therefore, PST needs two conditions for the two  $\Phi$ 's

- Localized at processor A
- The two eigenvalues satisfy  $\phi_1 = \phi_2 + 2n\pi$

Such that  $G(\tau) \Phi(0) = \exp(i\phi_1) \Phi(0)$ , becomes an eigenstate.

## Perfect state transfer in 1-D (PRL92,187902(2004))

The naturally-available spin Hamiltonian cannot perform PST, for instance,

$$H = \sum_{i=1} J_i (X_i X_{i+1} + Y_i Y_{i+1})$$

Where  $X, Y$  are Pauli's matrices. **J=constant-XY** model. Using J-W transformation, it becomes

$$H = \sum_{i=1} J_i (c_i^\dagger c_{i+1} + c_{i+1}^\dagger c_i)$$

$c$ 's are fermionic operators.

If we pre-engineer  $J$  such that  $J_i = \sqrt{i(N-i)}$

$$|\phi(0)\rangle$$
$$|\phi(0)\rangle_c$$

The Hamiltonian becomes  $H = JL_x$ , where

$$L_x = \sum_i \sqrt{i(N-i)} (c_i^\dagger c_{i+1} + c_{i+1}^\dagger c_i)$$

Mapping:  $l \leftrightarrow N_i$  in the way  $l = (N-1)/2, m = i - (N+2)/2$ ,  $L_x$  is the fermi representation of angular momentum.

Example  $N=4$  spin chain :

$$L_x = i \sum_i \sqrt{i(N-i)} (c_i^\dagger c_{i+1} - c_{i+1}^\dagger c_i)$$

$$L_z = \sum_i c_i^\dagger c_i (i - \frac{N+1}{2})$$

The Hamiltonian becomes  $H = JL_x$ , where

$$L_x = \sum_i \sqrt{i(N-i)} (c_i^\dagger c_{i+1} + c_{i+1}^\dagger c_i)$$

Mapping:  $l \leftrightarrow N-i$  in the way  $l = (N-1)/2, m = i - (N+1)/2$ ,  $L_x$  is the fermi representation of angular momentum.

Example  $N=4$  spin chain :

$$L_x = i \sum_i \sqrt{i(N-i)} (c_i^\dagger c_{i+1} - c_{i+1}^\dagger c_i)$$

$$L_z = \sum_i c_i^\dagger c_i (i - \frac{N+1}{2})$$

$Q_m \rightarrow Q'_m \rightarrow Q_m + Q'_m$

$(1278) \rightarrow (1278)$

$$\vec{C} = \sum \langle \alpha_m | \vec{L} | \alpha'_m \rangle a_m^\dagger a'_m$$

$$P_{AB}(\tau) = P_{AB}$$

$$\begin{aligned} \int_{\alpha_B} P_{AB}^A(0) &= \langle \alpha | \langle n | \psi(0) \rangle \langle \psi(0) | n \rangle \\ &= \langle \psi(0) | \alpha \times \beta | \psi(0) \rangle \\ &= \langle \psi(0) | U^\dagger(\tau) P_{AB} | \alpha \times \beta | P_{AB} U(0) | \psi \rangle \end{aligned}$$

The Hamiltonian becomes  $H = JL_x$ , where

$$L_x = \sum_i \sqrt{i(N-i)} (c_i^\dagger c_{i+1} + c_{i+1}^\dagger c_i)$$

Mapping:  $l \leftrightarrow N-i$  in the way  $l = (N-1)/2, m = i - (N+1)/2$ ,  $L_x$  is the fermi representation of angular momentum.

Example  $N=4$  spin chain :

$$L_x = i \sum_i \sqrt{i(N-i)} (c_i^\dagger c_{i+1} - c_{i+1}^\dagger c_i)$$

$$L_z = \sum_i c_i^\dagger c_i (i - \frac{N+1}{2})$$

$$|\phi(0)\rangle$$

$$|\phi(0)\rangle$$

$$|\rho(0)\rangle =$$

Evolution operator:

$$U(\tau) = \exp(-iJ\tau L_x)$$

When  $J\tau = \pi$ ,  $U(\pi/J) = \exp(-i\pi L_x)$  is a mirror-reflection operator, such that

$$U^\dagger(\pi/J)c_i^\dagger U(\pi/J) = r c_{N-i+1}^\dagger;$$

$$r = \exp\left(-i\pi \frac{N-1}{2}\right)$$

$r$  is called signature is nuclear physics.

$$N=1,5,9,\dots, \quad r=1$$

$$N=2,6,10,\dots, \quad r=-i$$

$$N=3,7,11,\dots, \quad r=-1$$

$$N=4,8,12,\dots, \quad r=i. \quad Z_4 \text{ group.}$$

Evolution operator:

$$U(\tau) = \exp(-iJ\tau L_x)$$

When  $J\tau = \pi$ ,  $U(\pi/J) = \exp(-i\pi L_x)$  is a mirror-reflection operator, such that

$$U^\dagger(\pi/J)c_i^\dagger U(\pi/J) = r c_{N-i+1}^\dagger;$$

$$r = \exp(-i\pi \frac{N-1}{2})$$

$r$  is called signature is nuclear physics.

$$N=1,5,9,\dots, \quad r=1$$

$$N=2,6,10,\dots, \quad r=-i$$

$$N=3,7,11,\dots, \quad r=-1$$

$$N=4,8,12,\dots, \quad r=i. \quad Z_4 \text{ group.}$$

State transfer can be done  $U(\pi/J)$

$$U(\pi/J) f(c_1^\dagger, \dots, c_n^\dagger) |00\dots\dots 00\rangle \\ = f(rc_N^\dagger, \dots, rc_{N-n+1}^\dagger) |00\dots\dots 00\rangle$$

If processor A has one qubit,

$$U(\pi/J) (a|0\rangle_1 + b|1\rangle_1) |\Phi(2, 3, \dots, N)\rangle \\ = |\Phi'(1, 2, \dots, N-1)\rangle (a|0\rangle_N + rb|1\rangle_N)$$

where  $\Phi$  is an arbitrary state of the rest of sites.

**If  $r=1$ , fidelity is one.**

# $Z_4$ interference (Wu et al PRA80, 012332 (2009))

State transfer can be done  $U(\pi/J)$

$$U(\pi/J) f(c_1^\dagger, \dots, c_n^\dagger) |00\dots\dots 00\rangle \\ = f(rc_N^\dagger, \dots, rc_{N-n+1}^\dagger) |00\dots\dots 00\rangle$$

If processor A has one qubit,

$$U(\pi/J) (a|0\rangle_1 + b|1\rangle_1) |\Phi(2, 3, \dots, N)\rangle \\ = |\Phi'(1, 2, \dots, N-1)\rangle (a|0\rangle_N + rb|1\rangle_N)$$

where  $\Phi$  is an arbitrary state of the rest of sites.

**If  $r=1$ , fidelity is one.**

# $Z_4$ interference (Wu et al PRA80, 012332 (2009))

Path independent, Size number  $N$  Dependent ( $4$  r's).

# PST with two-internal-level identical particles (Bosons or fermions) in optical lattices

(Wu et al PRA82,052339(2010))

# PST with two-internal-level identical particles (Bosons or fermions) in optical lattices (Wu et al PRA82,052339(2010))

The Hamiltonian is

$$H = \sum_{i,\sigma} J_i (c_{i\sigma}^\dagger c_{i+1\sigma} + c_{i+1\sigma}^\dagger c_{i\sigma}), \quad J_i = J \sqrt{i(N-i)}$$

↓ ↑

# PST with two-internal-level identical particles (Bosons or fermions) in optical lattices (Wu et al PRA82,052339(2010))

The Hamiltonian is

$$H = \sum_{i,\sigma} J_i (c_{i\sigma}^\dagger c_{i+1\sigma} + c_{i+1\sigma}^\dagger c_{i\sigma}), \quad J_i = J \sqrt{i(N-i)}$$

where we have neglected the on-site interaction and  $\sigma = \downarrow \uparrow$  denote the two internal levels.

# PST with two-internal-level identical particles (Bosons or fermions) in optical lattices (Wu et al PRA82,052339(2010))

The Hamiltonian is

$$H = \sum_{i,\sigma} J_i (c_{i\sigma}^\dagger c_{i+1\sigma} + c_{i+1\sigma}^\dagger c_{i\sigma}), \quad J_i = J \sqrt{i(N-i)}$$

where we have neglected the on-site interaction and  $\sigma = \downarrow \uparrow$  denote the two internal levels.

# PST with two-internal-level identical particles (Bosons or fermions) in optical lattices (Wu et al PRA82,052339(2010))

The Hamiltonian is

$$H = \sum_{i,\sigma} J_i (c_{i\sigma}^\dagger c_{i+1\sigma} + c_{i+1\sigma}^\dagger c_{i\sigma}), \quad J_i = J \sqrt{i(N-i)}$$

where we have neglected the on-site interaction and  $\sigma = \downarrow \uparrow$  denote the two internal levels.

We show that

$$L_x = \sum_{\sigma} \sqrt{i(N-i)} (c_{i\sigma}^\dagger c_{i+1\sigma} + c_{i+1\sigma}^\dagger c_{i\sigma})$$

is also the x-component of angular momentum, such that it can be used to do PST as the above.

The tunneling matrix elements  $J$ 's are usually independent of spin directions.

There is a qubit supported by spin-up and down, at each site.

The tunneling matrix elements  $J$ 's are usually independent of spin directions.

There is a qubit supported by spin-up and down, at each site.

The system is one of proposals for universal quantum computation, with qubit  $\downarrow$ . External field is used to manipulate individual spin (signal-qubit gate, commute with  $H$ ) and to make them interacted (two-qubit gate).

Quantum device is made of the same qubits, *no interface*.

PST can be made by H

$$|\phi\rangle_1 = a|\uparrow\rangle_1 + b|\downarrow\rangle_1 \xrightarrow{U(\pi/J)} |\phi\rangle_N = a|\uparrow\rangle_N + b|\downarrow\rangle_N$$

PST can be made by H

$$|\phi\rangle_1 = a|\uparrow\rangle_1 + b|\downarrow\rangle_1 \xrightarrow{U(\pi/J)} |\phi\rangle_N = a|\uparrow\rangle_N + b|\downarrow\rangle_N$$

- The present case cannot be translated into spin chain directly since JW transformation does not work.

Spin Chain: only two states

$|0\rangle_i$  and

present

$|00\rangle_i, c_i$

Two sta

serve as a qubit

$$c_{i\downarrow}^\dagger |00\rangle_i$$

Spin Chain: only two states

$|0\rangle_i$  and  $c_i^\dagger |0\rangle_i$ , serve as qubit

present case: four states

$|00\rangle_i$ ,  $c_{i\uparrow}^\dagger |00\rangle_i$ ,  $c_{i\downarrow}^\dagger |00\rangle_i$  and  $c_{i\uparrow}^\dagger c_{i\downarrow}^\dagger |00\rangle_i$

Two states:  $|\uparrow\rangle_i = c_{i\uparrow}^\dagger |00\rangle_i$  and  $|\downarrow\rangle_i = c_{i\downarrow}^\dagger |00\rangle_i$

serve as a qubit

PST can be made by H

$$|\phi\rangle_1 = a|\uparrow\rangle_1 + b|\downarrow\rangle_1 \xrightarrow{U(\pi/J)} |\phi\rangle_N = a|\uparrow\rangle_N + b|\downarrow\rangle_N$$

- The present case cannot be translated into spin chain directly since JW transformation does not work.
- Different from spin chain

The present case makes transfers via particles,  
while spin chain makes transfers via spin  
flipping

PST can be made by H

$$|\phi\rangle_1 = a|\uparrow\rangle_1 + b|\downarrow\rangle_1 \xrightarrow{U(\pi/J)} |\phi\rangle_N = a|\uparrow\rangle_N + b|\downarrow\rangle_N$$

- The present case cannot be translated into spin chain directly since JW transformation does not work.
- Different from spin chain

# Spin Chain: only two states

$|0\rangle_i$  and  $c_i^\dagger |0\rangle_i$ , serve as qubit

The present case can be extended to higher dimensions, while higher-D spin PST remains unclear (though there are many interesting explorations, for instance topologic structures of the networks, Feder, PRL 97,180502 (2006))

For 2D identical particles at site (i,k)

(Wu et al PRA 82,052339 (2010).)

First analytical model for higher D

$$H = J^{(1)} L_x^{(1)} + J^{(2)} L_x^{(2)}$$

$$L_x^{(1)} = \sum_{\sigma,k} \sqrt{i(N-i)} (c_{ik\sigma}^\dagger c_{i+1k\sigma} + c_{i+1k\sigma}^\dagger c_{ik\sigma})$$

$$L_x^{(2)} = \sum_{\sigma,i} \sqrt{k(M-k)} (c_{ik\sigma}^\dagger c_{ik+1\sigma} + c_{ik+1\sigma}^\dagger c_{ik\sigma})$$

$$[L_x^{(1)}, L_x^{(2)}] = 0$$

For 2D spin system, one can define

**similar**  $L_x$  's , but they don't commute

For 2D identical particles at site (i,k)

(Wu et al PRA 82,052339 (2010).)

First analytical model for higher D

$$H = J^{(1)} L_x^{(1)} + J^{(2)} L_x^{(2)}$$

$$L_x^{(1)} = \sum_{\sigma,k} \sqrt{i(N-i)} (c_{ik\sigma}^\dagger c_{i+1k\sigma} + c_{i+1k\sigma}^\dagger c_{ik\sigma})$$

$$L_x^{(2)} = \sum_{\sigma,i} \sqrt{k(M-k)} (c_{ik\sigma}^\dagger c_{ik+1\sigma} + c_{ik+1\sigma}^\dagger c_{ik\sigma})$$

$$[L_x^{(1)}, L_x^{(2)}] = 0$$

For 2D spin system, one can define

**similar**  $L_x$  's , but they don't commute

# Two-D networks $N=4, M=5$

For 2D identical particles at site (i,k)

(Wu et al PRA 82,052339 (2010).)

First analytical model for higher D

$$H = J^{(1)} L_x^{(1)} + J^{(2)} L_x^{(2)}$$

$$L_x^{(1)} = \sum_{\sigma,k} \sqrt{i(N-i)} (c_{ik\sigma}^\dagger c_{i+1k\sigma} + c_{i+1k\sigma}^\dagger c_{ik\sigma})$$

$$L_x^{(2)} = \sum_{\sigma,i} \sqrt{k(M-k)} (c_{ik\sigma}^\dagger c_{ik+1\sigma} + c_{ik+1\sigma}^\dagger c_{ik\sigma})$$

$$[L_x^{(1)}, L_x^{(2)}] = 0$$

For 2D spin system, one can define

**similar**  $L_x$  's , but they don't commute

Two-D networks  $N=4, M=5$

PST with the natural Heisenberg interaction with weakly attached processor A and B via RKKY.

## Summary

- Introduction, motivation
- State transfer with Naturally available interaction
- Perfect state transfer in 1-D with spin network
- PST in 1-D with identical particles with 2 levels
- PST in higher dimension with identical particles
- PST through natural Heisenberg chain with attached processors.
