Abstract:

# Overview

- Motivation
- Energy vs stability
- A simple model – perturbed motion stability

# Motivation

- Rehabilitation
- Robots
- Curiosity?

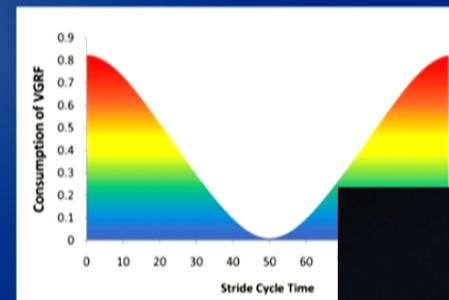

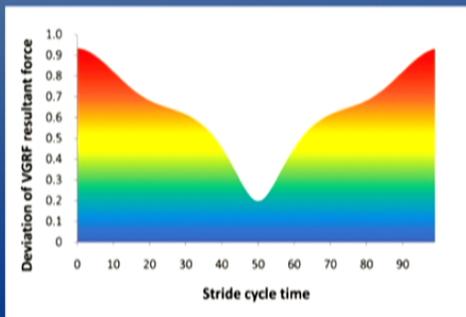

# Energy

Consideration of vertical ground reaction forces (VGRF) leads one to define the action function:

$$\Psi(t_0) = \sum_{t=1/f}^T (F_Z(t) + F_Z(t+t_0) - mg)^2$$

In a whole stride gravitational potential energy = 0, the total vertical mechanical energy is the kinetic energy  $E_k = \frac{1}{Tf} \sum \frac{1}{2}mv_i^2 > 0$

It turns out that we walk according to the Principle of Least Action, as defined above.

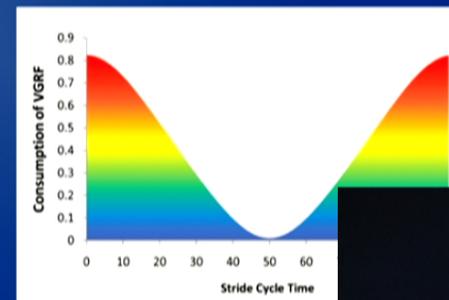

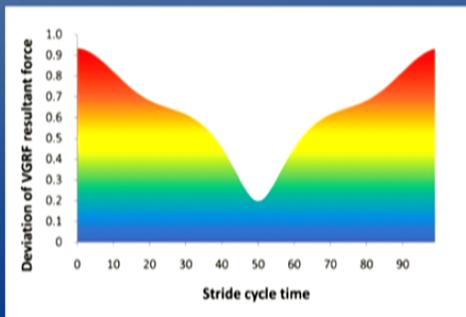

# Energy

Consideration of vertical ground reaction forces (VGRF) leads one to define the action function:

$$\Psi(t_0) = \sum_{t=1/f}^T (F_Z(t) + F_Z(t+t_0) - mg)^2$$

In a whole stride gravitational potential energy = 0, the total vertical mechanical energy is the kinetic energy  $E_k = \frac{1}{Tf} \sum \frac{1}{2}mv_t^2 > 0$

It turns out that we walk according to the Principle of Least Action, as defined above.

# So where's stability?

Apart from minimizing energy, we must also maintain stability in gait.

Not clear how relatively important the two notions are, so introduce destabilizing effects to study this.

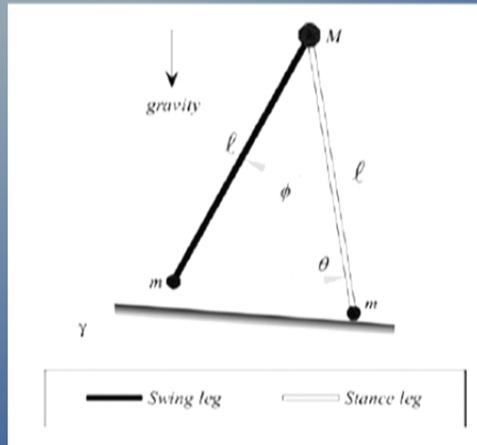

A simple choice is walking downhill.

Experiments – a more stable and energetically more costly gait ensues.

# A simple model – dynamic walker

Two phases of motion:

- Continuous leg swing
- Discrete foot-strike

The Hamiltonian for swing phase:

$$\mathbf{s} = [\theta \quad \phi \quad p_\theta \quad p_\phi]^T$$

$$H(\mathbf{s}) = (1 + \beta) \cos(\gamma - \theta) - \beta \cos(\gamma - \theta + \phi) + \frac{p_\theta^2 + (2 - 2 \cos \phi) p_\theta p_\phi + (2 - 2 \cos \phi + \beta^{-1}) p_\phi^2}{2 + 2\beta \sin^2 \phi}$$

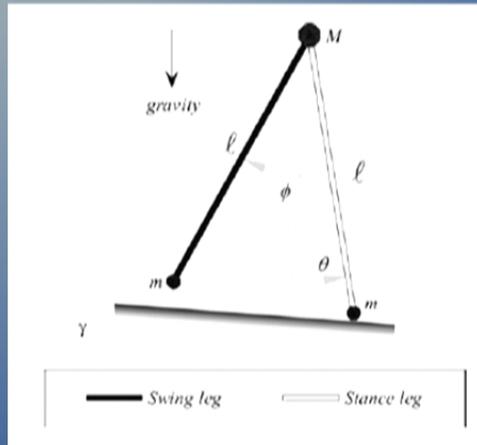

Foot-strike: inelastic collision and angular momentum conservation

$$\phi - 2\theta = 0$$

Resultant EoM's complicated and not enlightening.

# A simple model – dynamic walker

Two phases of motion:

- Discrete foot-strike

The Hamiltonian for swing phase:

$$\mathbf{s} = [\theta \quad \phi \quad p_\theta \quad p_\phi]^T$$

$$H(\mathbf{s}) = (1 + \beta) \cos(\gamma - \theta) - \beta \cos(\gamma - \theta + \phi) + \frac{p_\theta^2 + (2 - 2 \cos \phi) p_\theta p_\phi + (2 - 2 \cos \phi + \beta^{-1}) p_\phi^2}{2 + 2\beta \sin^2 \phi}$$

Foot-strike: inelastic collision and angular momentum conservation

$$\phi - 2\theta = 0$$

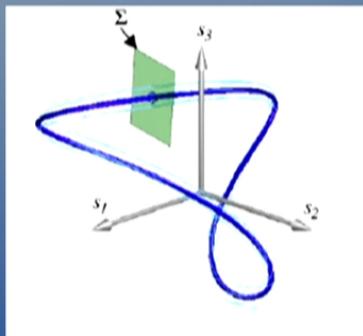

Resultant EoM's complicated and not enlightening.

# Perturbations and Stability

Stability problem of the solutions to walking simplified by Poincare maps and Poincare sections

$$\mathbf{s}_{i+1}^{\Sigma} = \mathbf{P}(\mathbf{s}_i^{\Sigma})$$

Allows to consider stability discretely instead of continuously, reduces dimensionality

Simplest solution:  $\mathbf{s}_{eq}^{\Sigma} = \mathbf{P}(\mathbf{s}_{eq}^{\Sigma})$

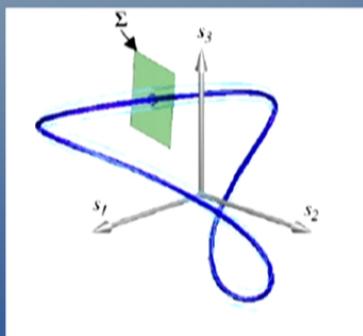

Need a criterion for stability!

# Perturbations and Stability

Stability problem of the solutions to walking simplified by Poincare maps and Poincare sections

$$\mathbf{s}_{i+1}^{\Sigma} = \mathbf{P}(\mathbf{s}_i^{\Sigma})$$

Allows to consider stability discretely instead of continuously, reduces dimensionality

Simplest solution:  $\mathbf{s}_{eq}^{\Sigma} = \mathbf{P}(\mathbf{s}_{eq}^{\Sigma})$

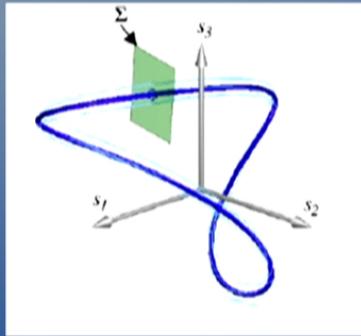

Need a criterion for stability!

# Perturbations and Stability

$$\mathbf{s}_{i+1}^{\Sigma} = \mathbf{P}(\mathbf{s}_i^{\Sigma})$$

Allows to consider stability discretely instead of continuously, reduces dimensionality

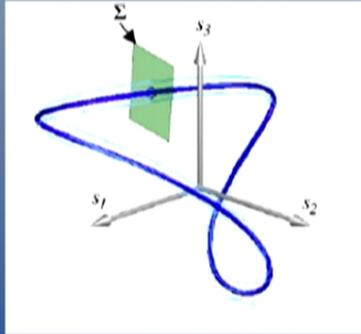

Simplest solution:  $\mathbf{s}_{eq}^{\Sigma} = \mathbf{P}(\mathbf{s}_{eq}^{\Sigma})$

Need a criterion for stability!

# Orbital Stability

Look at the Poincare intersection – if points stay close to equilibrium then stable, otherwise unstable

Quantified way: estimate the Jacobian of the map and find eigenvalues

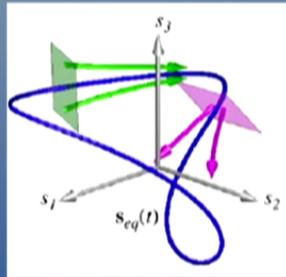

If the absolute value of any eigenvalue is  $> 1$  then the equilibrium is unstable.

# Local Dynamic Stability

If the system is described by

$$\dot{\mathbf{s}} = \mathbf{F}(\mathbf{s})$$

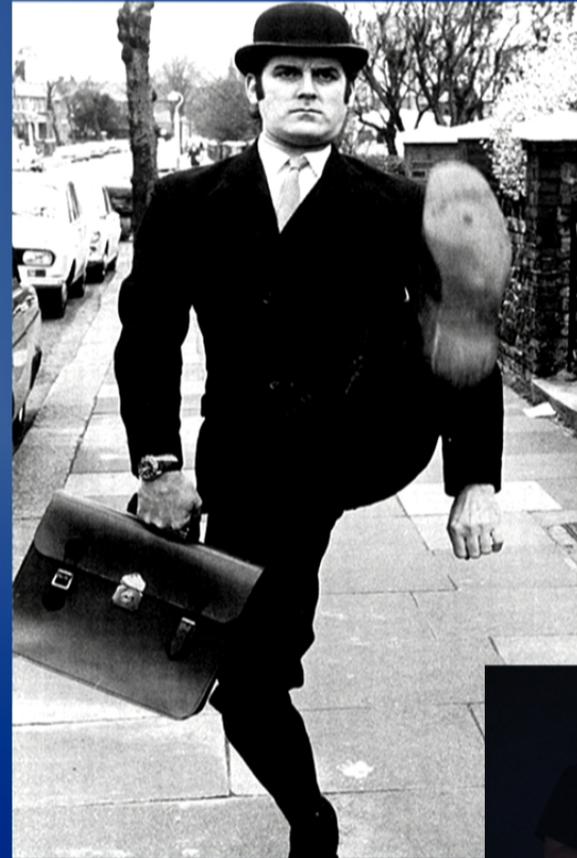

Then we want to look at eigenvalues of the Jacobian of  $\mathbf{F}$  evaluated along the equilibrium solution

$$D_s \mathbf{F}|_{\mathbf{s}_{eq}(t)}$$

If the real parts of all eigenvalues of the Jacobian are  $< 0$  at time  $t$ , then the solution is locally stable at  $t$ . Otherwise it is locally unstable.

# Summary

- Human gait is governed by minimizing the energy cost and maximizing stability.
- Relative importance of the two is not known, so study perturbed systems.
- Experimental results support in most cases the predictions of the simplified models
