

Title: Fundamental physics with muons

Date: Oct 21, 2014 01:00 PM

URL: <http://pirsa.org/14100115>

Abstract: I will review applications of the muon as a probe for new phenomena. Topics to be discussed include the free muon decay and the determination of the Fermi constant; the anomalous magnetic moment of the muon; and searches for lepton flavor violation such as $\mu \rightarrow e + \gamma$, $\mu \rightarrow 3e$, and the muon-electron conversion, with special emphasis on the modification of the muon decay by the atomic binding.

Outline

Three promising directions in low-energy searches:

- * anomalous magnetic moments (muon vs electron)
- * electric dipole moments (electron)
- * lepton flavor violation (muon \rightarrow electron)

Outline

Three promising directions in low-energy searches:

Outline

Three promising directions in low-energy searches:

- * anomalous magnetic moments (muon vs electron)
- * electric dipole moments (electron)
- * lepton flavor violation (muon \rightarrow electron)

The puzzle of the muon magnetic moment

The 3.6 sigma discrepancy persists,

$$a_{\mu}^{\text{exp}} - a_{\mu}^{\text{SM}} = 287(80) \times 10^{-11} \quad \text{PRD 86, 095009 (2012)}$$

This is rather large when compared with other bounds on New Physics:

Muon MDM
$$d_{\mu} \sim \frac{e}{2m_{\mu}} a_{\mu}^{\text{NP}} \sim 3 \cdot 10^{-22} \text{ e} \cdot \text{cm}$$

Muon-electron transition moment $|d_{\mu \rightarrow e}| < 4 \cdot 10^{-27} \text{ e} \cdot \text{cm} \quad \text{MEG 2013}$

Electron EDM $|d_e| < 8.7 \cdot 10^{-29} \text{ e} \cdot \text{cm} \quad \text{ACME 2014}$

How can $g_{\mu}-2$ be checked?

New experiment at Fermilab

New experimental concept at J-PARC

Can we use $g_{\mu}-2$?

How can $g_{\mu}-2$ be checked?

New experiment at Fermilab

Magnetic moment of the electron

$$a_e = \frac{g_e - 2}{2}$$

Measured with relative error $25 \cdot 10^{-11}$

Phys. Rev. Lett. 100, 120801 (2008)

Provides the fine structure constant with the same precision,

$$\alpha^{-1}(a_e) = 137.0359991736(331)(86)$$

Phys. Rev. Lett. 108, 111807 (2012)

Experimental error dominates (for now)

Numerical errors from 4- and 5-loop diagrams

Kinoshita

How to use g_e-2 to check $g_\mu-2$?

If the muon anomaly is due to New Physics, the expected effect for the electron is likely smaller by

$$\frac{g_e^2}{m_e^2} \sim \frac{1}{43000}$$

$$\Delta a_\mu \sim 287 \cdot 10^{-11} \rightarrow \Delta a_e \sim 7 \cdot 10^{-14}$$

This means relative uncertainty $\frac{\Delta a_e}{a_e} \sim 7 \cdot 10^{-11}$

and requires a factor of 4 improvement of the latest measurement.

In addition, an independent determination of the fine structure constant is needed, with matching precision.

How to use g_e-2 to check $g_\mu-2$?

This is a smaller version of the slide shown above, containing the same title, equations, and diagrams. It includes the title 'How to use g_e-2 to check $g_\mu-2$?' and the equation $R_\infty = \frac{m_e c \alpha^2}{2h}$. It also features the diagram showing the decomposition of α^2 into its constituent terms with associated precision values and a legend for the Rb atom diagram.

Similar binding corrections needed for the muonium: input to g-2

Another source of alpha: highly-charged ions

$$g \simeq 2 - \frac{2(Z\alpha)^2}{3} \longrightarrow \frac{\delta\alpha}{\alpha} \simeq \frac{1}{(\alpha Z)^2} \sqrt{(\delta g_{\text{exp}})^2 + (\delta g_{\text{th}})^2} \quad \text{large } Z \text{ favorable}$$

Hydrogen-like lead

Boron-like lead

There is a combination of g-factors in both ions where the sensitivity to the nuclear structure largely cancels, but the sensitivity to alpha remains.

Much interesting theoretical work remains to be done!

Remarks on d_e

Molecules: great new player; but enhancement factors very tricky
One way to check: hyperfine structure (YbF)

Molecules are a very new field; many improvements possible
(sources!)

An even newer field: molecular ions.

Challenge for theorists: "enhancement factors": this is a new frontier for
quantitative studies in molecules.

History of the electron EDM

Efforts in LFV searches

Historical overview of selected CLFV searches:

New physics:

Conversion: probes also non-dipole interactions

So far, we have only talked about dipole interactions.
There are also vectors and scalars.

They are not (directly) probed by processes with external photons,
by gauge invariance requirements.

New process: muon-electron conversion
(as well as $\mu \rightarrow eee$)

Variety of mechanisms:

Variety of mechanisms:

Bound muon decay has been measured: TWIST/TRIUMF

- Future $\mu \rightarrow e$ conversion experiments plan to study negative muons bound to Al
- Most precise measurement ever of the muon decay-in-orbit spectrum
- Theoretical predictions include higher-order contributions from the muon+nucleus potential
- Need to include the $O(\alpha)$ radiative corrections that arise from the interaction between the muon and the outgoing electron

Conclusions

Great opportunities for precise theoretical studies in low-energy physics:

- bound electron g -factor: complements a vigorous experimental program in Mainz, Heidelberg and GSI Darmstadt
- muon decay: background for μ - e conversion searches; theoretically interesting
- many atomic/molecular structure studies needed, eg for electric dipole searches
