Probing the magnetic field in the vicinity of supermassive AGN black holes with RadioAstron at 33 μs angular resolution

J. L. Gómez, A. Lobanov, G. Bruni, U. Bach, Y. Kovalev, K. Sokolovsky, A. P. Marscher, S. G. Jorstad, for the KSP team

RadioAstron

Space-VLBI mission capable of achieving an angular resolution of $\sim 10 \mu\text{s}$ at $\lambda=1.3 \text{ cm}$.

Polarization Key Science Program

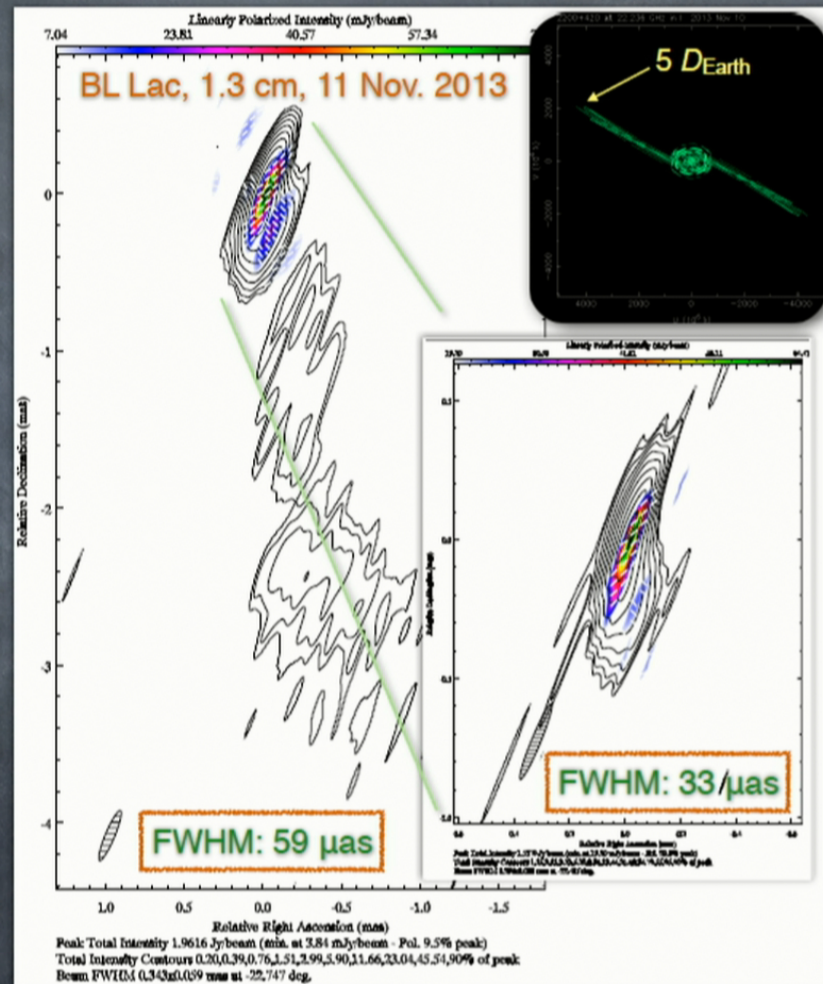

Aimed to probe the innermost regions of AGN jets and their magnetic field. First year observed targets: BL Lac, 3C273, 3C279, OJ287.

BL Lac at 1.3 cm with RadioAstron

First successful space-VLBI observations at 1.3 cm, with ground-space detections for up to $5 D_{\text{Earth}}$ (4800 M λ), achieving a maximum angular resolution of $33 \mu\text{s}$ (2600 R_s), the highest to date.

BL Lac shows a bent structure in the innermost 0.3 mas, with two components in polarization showing orthogonal EVPAs.

Confirmed RadioAstron polarization capabilities to probe AGN jets with angular resolutions of $\leq 30 \mu\text{s}$

M87 Imaging with Sparse Modeling

Fumie Tazaki¹, Mareki Honma¹, Kazunori Akiyama^{1,2}, Kazuhiro Hada¹, Shiro Ikeda³, Makoto Uemura⁴, & Seijyu Kudo⁵ (¹NAOJ, ²U. Tokyo, ³ISM, ⁴Hiroshima U., ⁵Kyushu U.)

Sparse modeling:

- ❖ A technique which selects an optimum sparse solution from linear ill-posed equations.
- ❖ A breakthrough in the detailed imaging with VLBI, which has been highly affected by the incomplete sampling of visibilities.

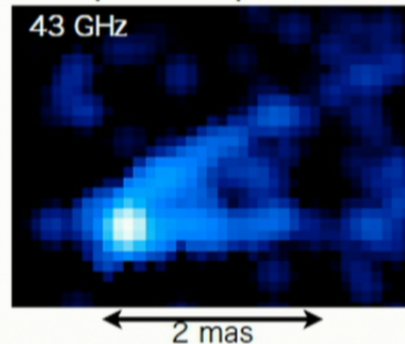

Standard Method

Limb-brightening and counter-jet-like structures in LASSO images!!

LASSO

(a technique in the sparse modeling)

Confirmation of counter-jet-like structure

Model images

LASSO images

Counter-jet structure definitely exists!!

The position of the black hole is determined.

Preliminary

SUMMARY

Over the past decade much work in the field of black hole astrophysics has been focused on the so-called Fundamental Plane of Black Hole Accretion (FP); a relation between the X-ray and Radio luminosities and masses of weakly accreting black holes that applies to supermassive black holes and black hole binaries alike. Here we choose to investigate two individual sources from this FP in more detail: Sgr A*, the supermassive black hole at the centre of the Galaxy, and A0620-00, a black hole binary in the Galactic plane, both of which are weakly accreting and fit on the FP relation. We present a new joint fitting method using a semi-analytical jet model and multi-wavelength data obtained from both sources: including 20 X-ray flare observations of Sgr A* as a result of a 20M2 observing campaign of the Galactic centre, the X-ray Volcano Project. If the FP relation holds then it implies black holes at the same Eddington scaled mass accretion rate should regulate their output in the same way regardless of the black hole mass. As well as breaking model degeneracy in spectral fitting, this work can tell us more about the importance of dynamical modality near FP black holes, and this could advance our understanding of what needs to be considered in our modelling of Sgr A*'s emission mechanisms.

MOTIVATION

- The Fundamental Plane of Black Hole Accretion (FP): a relation between the X-ray and Radio luminosities and masses of weakly accreting black holes (< 1% Eddington rate), from active galactic nuclei (AGN) to black hole binaries (BHs), proposed, and found empirically (see e.g. Markoff et al. (2005), Jarvis & Szymon (2005), Merloni et al. (2005), Hada et al. (2004), and Kording et al. (2005)).
- Statistical studies indicate jet emission explains relation (though an inverse correlation component from the photos or ADAF component may dominate at low X-ray energies), given by $\log L_x = (1.45 \pm 0.04) \log L_{\text{Edd}} - (0.88 \pm 0.05) \log M_{\text{BH}} - 6.07 \pm 1.10$
- Sgr A* appears to lie on FP during 'quiet' states, but not during outburst/episodes states (see Fig. 1), we want to investigate Sgr A*'s relationship to the FP and its underlying physical processes, can we learn something about our observations of emission close to the black hole from processes around other black holes? We fit a wide low-mass jet model (Markoff et al. 2005) to spectra taken from Sgr A* and a black hole binary on the FP A0620-00.

Fig. 1. Fundamental Plane relation adapted from Plotkin et al. (2012). Shows in the same colour X-ray luminosity against the radio luminosity, but highlights our black hole binaries, and all other data points represent AGN of different types/bands.

THE MODEL: AGNJET

- Jet model developed in series of papers - e.g. Falcke (1996), Hada & Markoff (2001).
- Description of the model and its parameters can be found in Markoff et al. (2005).
- Calculate evolution of plasma outflow using hydrodynamical (Euler) equations, with a point of shock acceleration, and calculate radiative emission - synchrotron (power-law) and power-law (exponentially thick & thin), synchrotron self-compton (SSC), blackbody components (emission/absorption disc).
- Fitting performed using ISIS, X-ray data analysed using software.
- Based on other individual sources with positive results - e.g. M81 (AGO & GX 339-4 (EHE) - Fig. 2).

Fig. 2. Example of previous model fits to M81 (left: Markoff et al. 2005) and GX 339-4 (right: Hada et al. 2005). Shows in the upper range in each plot, with radio, X-ray optical and X-ray data fit with the model, and model components are shown individually with: orange line: power-law synchrotron emission, light green: synchrotron self-compton, grey: power-law synchrotron, grey in red: light blue = SSC, other colours represent the same as synchrotron.

SINGLE FITTING RESULTS

- Have an issue related fits to A0620-00 (EHE) in the Galactic plane, fits on the FP, notice the model degeneracy: two fits with different dominant components match the data equally well.
- Diagram shows location from which the different components emit.

Fig. 3. Two different options of A0620-00 fit with the AGNJET model. Shows in this figure range, and model components overlaid to model emission. Observed in each plot with black, synchrotron (SSC) component (orange) and synchrotron component (light green). Shows the jet in red, blue, purple. Also in red: jet in blue, purple, red.

JOINT FITTING

- Fig. 4 shows an example of a joint fit (three previous results). More certain model.
- Parameters are tied between the two data sets (e.g. the size of the jet nozzle, the location of acceleration in the jet - parameters that may depend only on mass/accretion rate), so they vary in unison during the fit.
- The fit may help us understand the universal regulation of power in black holes, providing some physical insight into the FP.
- Able to distinguish between degenerate models for each source in the fit.
- Fit now being conducted with improved X-ray data from Sgr A*, a result of 20M2 X-ray Volcano Project (Halpern et al. 2012) - Fig. 5.

Fig. 4. Example of joint fitting to fit of our AGNJET model (Markoff et al. 2005) to spectra of Sgr A* (left) and A0620-00 (right). Shows in the upper range in each plot, with radio, X-ray optical and X-ray data fit with the model, and model components are shown individually with: orange line: power-law synchrotron emission, light green: synchrotron self-compton, grey: power-law synchrotron, grey in red: light blue = SSC, other colours represent the same as synchrotron.

- Very interesting of jet of stars with EHE fitting parameters on Sgr A* in 2012 (Halpern et al. 2012). Shows in this figure spectra in orange/red, with an average of 10 flares in 2012 shown in blue, and general spectra in green. We could look to an independent, published spectrum - but general spectra in green. We could look to an independent, published spectrum - but general spectra in green. We could look to an independent, published spectrum - but general spectra in green. We could look to an independent, published spectrum - but general spectra in green.

Fig. 5. Very interesting of jet of stars with EHE fitting parameters on Sgr A* in 2012 (Halpern et al. 2012).
