GaryFest UCSB April '15

UCSB

## Plan for this talk...

---

- 'Quick' review of AdS/CFT and a confinement - I will emphasise it as a tool to study CFT on curved spaces.
- Small black holes
- Scalar fluctuations as observables

## Motivating question

- Suppose we put a (strongly coupled) CFT on an arbitrary space, normalized in some way (eg. by volume, or by curvature etc...)
- **Question:** is there a smallest gap, and what space(s) achieve it?
- Free field example; conformal scalar - smallest for sphere if fix  $\bar{R}_{min}$

$$\nabla^2 \psi = \frac{D-2}{4(D-1)} \bar{R} \psi \quad \Rightarrow \quad \omega_{min}^2 \geq \frac{D-2}{4(D-1)} \bar{R}_{min}$$

## AdS-CFT

- **Conjecture (Maldacena):** certain classes of (special) CFTs are **dual** to gravitational theories (possibly higher spin or string theories) in spacetimes that asymptote locally to AdS.
- These CFTs are characterized by an effective number of d.o.f,  $c_{eff}$ .
- For large  $c_{eff}$ , these strongly coupled CFTs have a dual which is semiclassical gravity + matter fields, with locally AdS asymptotics.
- They always admit a *universal gravity sector*; for a  $D$ -dimensional CFT, this sector is described by  $(D + 1)$ - dimensional Einstein metrics;

$$R_{\mu\nu}^{(D+1)} = -\frac{D}{\ell^2}g_{\mu\nu}$$

$$c_{eff} = \frac{\ell^{D-1}}{16\pi G_{D+1}}$$

- Asymptotics encode the spacetime the CFT lives on - this provides a very powerful tool to study strongly coupled CFTs on curved spacetimes.

## AdS-CFT

---

- A powerful way to use AdS-CFT is as a tool to geometrize strongly coupled QFT questions.
- This is particularly powerful in time dependent OR spatially dependent situations.

(for a review on AdS/CFT for CFTs on curved spacetimes see [ Marolf, Rangamani, TW '13])

## Confinement

- A CFT naturally has no inherent energy scale. However putting the CFT on a curved space can introduce a scale. In suitable cases the CFT then develops an energy gap.
- We will call this 'confinement' as in the case the CFT is a gauge theory, this can be thought of as exhibiting confining behaviour.
- Canonical example is global AdS, [Witten '98]

$$ds^2 = - \left( \frac{\rho^2}{\ell^2} + 1 \right) dt'^2 + \left( \frac{\rho^2}{\ell^2} + 1 \right)^{-1} d\rho^2 + \rho^2 d\Omega_{(D-1)}^2$$

- Vacuum geometry dual to CFT on  $\mathbb{R}_t \times S^{D-1}$

$$ds_{CFT}^2 = -dt^2 + \mathcal{R}^2 d\Omega_{(D-1)}^2$$

## Features of confinement - scalar fluctuations

- Consider fluctuations of a bulk scalar (ignore backreaction),  $\nabla^2 \phi = m^2 \phi$  with 'Dirichlet' b.c.s

- This is dual to a CFT scalar operator  $\mathcal{O}$ , dimension  $\Delta > D/2$

$$\Delta(\Delta - D) = \ell^2 m^2$$

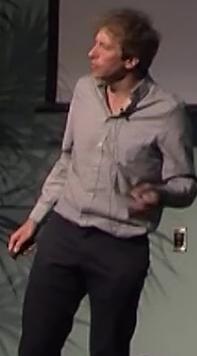

- Since bulk is static we can consider harmonic modes in time;  $\phi(t, x^i) = f(x^i) e^{i\omega t}$
- Ex - global AdS; then spectrum of normal modes is discrete, with a gap;

$$\omega_{min}^2 = \frac{\Delta^2}{\mathcal{R}^2}$$

## Hawking-Page

---

- Hawking and Page studied global AdS-Schwarzschild - one parameter family of static black holes.
- Large energy/mass solution is universal (~ fluid/gravity correspondence).
- There is a small black hole ~ flat space Schwarzschild.
- Consequently there is a minimum black hole temperature.
  
- Black holes describe the behaviour of part of the spectrum of the CFT.
- Hawking-Page behaviour corresponds to 1st order deconfinement transition.

## Another confining dual - due to Gary (and Rob)

- A nice example of a confining bulk geometry is the 'AdS-soliton' [Horowitz, Myers '98] - a Wick rotation of planar AdS-Schwarzschild - [Witten '98]

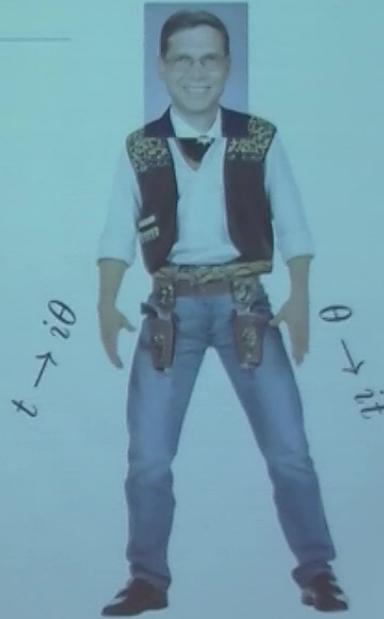

- Consider a boundary metric;  $\mathbb{R}_t \times \mathbb{T}^{D-2} \times S^1$ , take the  $S^1$  to have length  $L$

- The a smooth bulk metric is;

$$ds^2 = \frac{\ell^2}{z^2} \left( \frac{1}{1 - \left(\frac{z}{z_0}\right)^D} dz^2 - dt^2 + ds_{\mathbb{T}^{D-2}}^2 + \left(1 - \left(\frac{z}{z_0}\right)^D\right) d\theta^2 \right)$$
$$z_0 = \frac{D}{2} L$$

- Note it closes off smooth at  $z = z_0$ ; there are not other ends to the geometry.
- Spectrum is gapped, small black holes exist. [Figueras, Tunyasuvunakool '14]

'Gary the Kid'

UCSB

## Another confining dual - due to Gary (and Rob)

- A nice example of a confining bulk geometry is the 'AdS-soliton' [Horowitz, Myers '98] - a Wick rotation of planar AdS-Schwarzschild - [Witten '98]

- Consider a boundary metric;  $\mathbb{R}_t \times \mathbb{T}^{D-2} \times S^1$ , take the  $S^1$  to have length  $L$

- The a smooth bulk metric is;

$$ds^2 = \frac{\ell^2}{z^2} \left( \frac{1}{1 - \left(\frac{z}{z_0}\right)^D} dz^2 - dt^2 + ds_{\mathbb{T}^{D-2}}^2 + \left(1 - \left(\frac{z}{z_0}\right)^D\right) d\theta^2 \right)$$
$$z_0 = \frac{D}{2} L$$

- Note it closes off smooth at  $z = z_0$ ; there are not other ends to the geometry.
- Spectrum is gapped, small black holes exist. [Figueras, Tunyasuvunakool '14]

General case

UCSB

## General picture

- Suppose we consider our  $CFT_D$  on a static spacetime  $\mathbb{R}_t \times \Sigma$

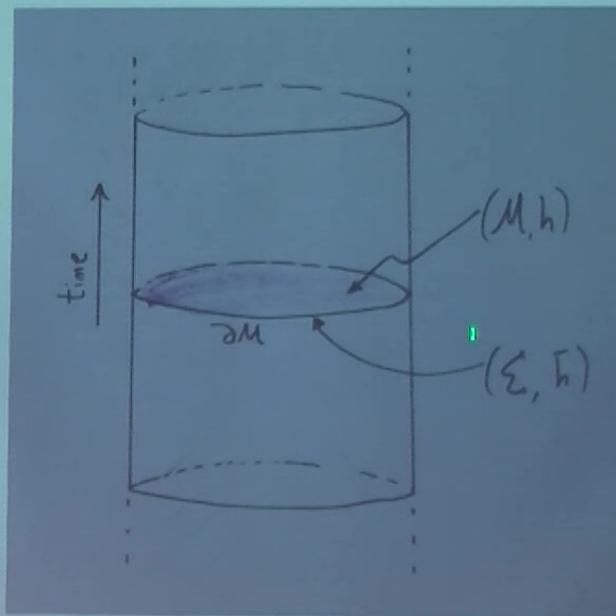

$$ds_{CFT}^2 = -dt^2 + \bar{h}_{ab} dx^a dx^b$$

- Assume the bulk is also static, and given in terms of a smooth Riemannian  $(\mathcal{M}, h)$  with boundary  $\Sigma$  - the 'base';

$$ds^2 = \frac{\ell^2}{Z^2(x)} (-dt^2 + h_{ij}(x) dx^i dx^j)$$

- Then  $Z$  is a function on  $\mathcal{M}$ , that vanishes on the boundary,  $\partial\mathcal{M}$
- Then  $\Sigma = \partial\mathcal{M}$  and  $\bar{h}$  is the metric induced by  $h$  on the boundary.
- Note that  $\partial/\partial t$  smoothly extends to the boundary.

## General picture

UCSB

## Bulk Einstein equations

- We may write the bulk Einstein equations covariantly over  $\mathcal{M}$

$$R_{ij} = -\frac{(D-1)}{Z} \nabla_i \partial_j Z$$
$$R = \frac{D(D-1)}{Z^2} (1 - (\partial Z)^2)$$

- Later we consider scalar fluctuations; a mode  $\phi(t, x^i) = f(x^i) e^{i\omega t}$  obeys the eigenvalue problem in  $\mathcal{M}$

$$-Z^{D-1} \nabla^i \left( \frac{1}{Z^{D-1}} \partial_i f \right) + \frac{\ell^2 m^2}{Z^2} f = \omega^2 f$$

## Confining bulks

- Define a 'confining vacuum bulk' as;
  - Smooth  $(\mathcal{M}, h)$  and  $Z > 0$  only vanishing on  $\partial\mathcal{M}$  at the asymptotic AdS boundary. Note  $\partial/\partial t$  globally timelike.
  - $(\mathcal{M}, h)$  has only the boundary associated to asym AdS, with no other boundaries or asymptotic regions (so has finite volume).
  - Assume boundary  $\Sigma = \partial\mathcal{M}$  is closed (ie. cmpt, no boundary)
- Example; global AdS and the AdS-soliton [Horowitz, Myers '98]
- More generally can take any (?) smooth closed  $\Sigma$  and we expect a static bulk vacuum solution to exist.

## Confining bulks

- One can perform an asymptotic analysis near the conformal boundary.
- This shows the boundary metric  $\bar{h}_{ab}$  Ricci tensor,  $\bar{R}_{ab}$ , is related to the optical one at the boundary as;

$$R_{zz}|_{z=0} = \frac{1}{D-2}\bar{R}, \quad R_{ab}|_{z=0} = \frac{D-1}{D-2}\bar{R}_{ab} \quad \Rightarrow \quad R|_{z=0} = \frac{D}{D-2}\bar{R}$$

- We also see scalar fluctuations behave as;  $f \sim Z^\Delta$
- Crucial point we use is the the base Ricci scalar obeys;

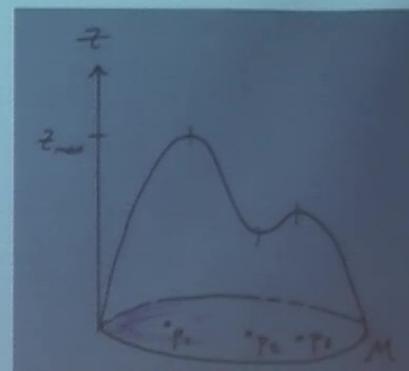

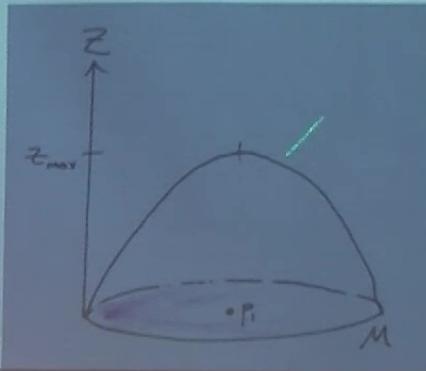

$$\nabla^2 R - \frac{(D-3)}{Z} \partial^i Z \partial_i R \leq 0$$

- Hence it is **minimized** on the boundary and;

$$R_{min} = \frac{D}{D-2} \bar{R}_{min}$$

## Bulk redshift

- The function  $Z$  determines the local redshift in the bulk.  $Z(x)/\ell$  relates the proper time at  $x^i$  to the bulk coordinate time  $t$ , and thus the CFT time.
- Take extrema of  $Z$  at points  $p_{(n)}$ . Let the maximum value be  $Z_{max}$
- Then;  $D(D-1) = Z_{(n)}^2 R_{(n)}$  and these points cannot be minima of  $Z$

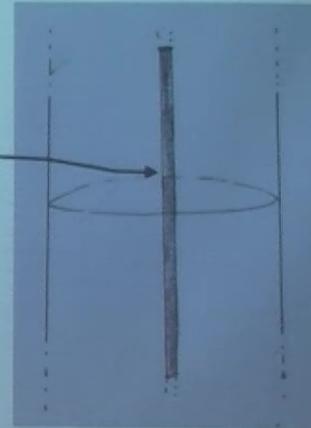

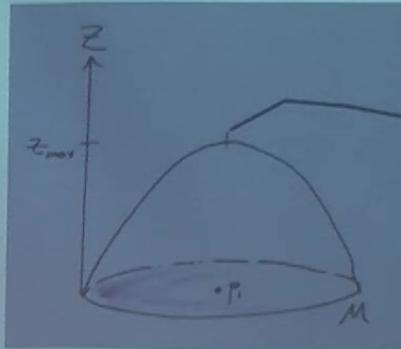

## Small black holes

- A timelike geodesic, proper time  $\tau$ , executes a motion on  $\mathcal{M}$

$$\frac{d^2 x^i}{d\tau^2} + \Gamma^i{}_{jk} \frac{dx^j}{d\tau} \frac{dx^k}{d\tau} = \partial^i (Z^2) + \frac{4}{Z} \partial_j Z \frac{dx^j}{d\tau} \frac{dx^i}{d\tau}$$

- Hence we may patch in a very small black hole at the extrema pts,  $p_{(n)}$ , of  $Z$

## Small black holes

- Locally these 'tiny' black holes are simply  $(D + 1)$ -dim'l Schwarzschild

- Hence;  $S_{local} = \frac{1}{4G} \Omega_{(D-1)} r_h^{D-1}$        $M_{local} = \frac{D-1}{16\pi G} \Omega_{(D-1)} r_h^{D-2}$

- The CFT entropy is equal to this local entropy;  $S_{CFT} = S_{local}$

- Recall the CFT time is related to bulk time via  $Z(x)$ , so;  $E_{CFT} = \frac{\ell}{Z_{(n)}} M_{local}$

- Thus these states due to tiny black hole at  $P_{(n)}$  gives rise to a behaviour;

$$\tilde{E}_{CFT} = \frac{a_D}{Z_{(n)}} \tilde{S}_{CFT}^{\frac{D-2}{D-1}}$$

$$\tilde{S}_{CFT} = \frac{1}{c_{eff}} S_{CFT}$$

$$\tilde{E}_{CFT} = \frac{1}{c_{eff}} E_{CFT}$$

$$a_D = \frac{(D-1)\Omega_{(D-1)}}{(4\pi\Omega_{(D-1)})^{\frac{D-2}{D-1}}}$$

## Small black holes

- Now using;  $D(D-1) = Z_{(n)}^2 R_{(n)}$  we directly see,

$$\frac{D}{D-2} \bar{R}_{min} = R_{min} \leq \frac{D(D-1)}{a_D^2} \tilde{E}_{CFT}^2 \bar{S}_{CFT}^{-\frac{2(D-2)}{D-1}} \leq R_{max}$$

- The upper bound is nice, but relies on knowing detail of the bulk, albeit a local geometric invariant.
- The lower bound is more interesting as it involves *only CFT quantities*. The only assumption is that the bulk takes the 'confining vacuum' form.
- The bounds are sharp and saturated for global AdS (for which  $R = \text{const}$ ).

## Scalar fluctuations

- Write a scalar wavefunction as;  $f(x) = Z^\Delta J(x)$  where  $J$  is bounded.

- Using the bulk equations;  $0 = \nabla^2 J + \frac{2\Delta - D + 1}{Z} \partial^i Z \partial_i J + \left( \omega^2 - \frac{\Delta^2}{D(D-1)} R \right) J$

- Integrating over  $\mathcal{M}$  we obtain, (recalling  $\Delta > D/2$ ),

$$\omega^2 = \frac{\int_{\mathcal{M}} \sqrt{h} Z^\beta \left( (\partial J)^2 + \frac{\alpha^2}{D(D-1)} R J^2 \right)}{\int_{\mathcal{M}} \sqrt{h} Z^\beta J^2}$$

- This directly gives a lower bound, and by a variational argument with trial wavefunction  $J = \text{const}$  a upper bound;

$$\frac{\Delta^2 R_{\min}}{(D-1)(D-2)} = \frac{\Delta^2 R_{\min}}{D(D-1)} \leq \omega_{\min}^2 \leq \frac{\Delta^2 R_{\max}}{D(D-1)}$$

- Similar to small bh bounds - again lower bound *involves only CFT quantities*, and the bounds are sharp and saturated for global AdS.

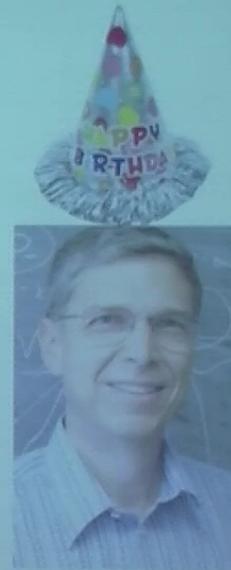

## Summary

- We have considered the CFT on  $\mathbb{R}_t \times \Sigma$ , with  $\Sigma$  closed. Such spaces may induce an 'confining behaviour' about the vacuum state.
- We have derived lower bounds for these controlled by the minimum Ricci scalar of  $\Sigma$ .

$$\frac{\Delta^2 \bar{R}_{min}}{(D-1)(D-2)} \leq \omega_{min}^2 \qquad \frac{D}{D-2} \bar{R}_{min} \leq \frac{D(D-1)}{a_D^2} \tilde{E}_{CFT}^2 \bar{S}_{CFT}^{-\frac{2(D-2)}{D-1}}$$

- We have assumed 'confining bulk' - is there a gap or small black holes without this assumption?
- Interesting corollary; given  $\Sigma$  normalized by the value of  $\bar{R}_{min} > 0$ , then minimal gap (for scalar fluctuations) is for  $\Sigma = S^{D-1}$  (with 'confining bulk assumption').

Happy Birthday Gary!

UCSB
