

Title: Emergent network geometry and quantum statistics

Date: Sep 15, 2016 02:30 PM

URL: <http://pirsa.org/16090029>

Abstract: <p>Abstract: Complex networks describe interacting systems ranging from the brain to the Internet. While so far the geometrical nature of complex networks has been mostly neglected, the novel field of network geometry is crucial for gaining a deeper theoretical understanding of the architecture of complexity. At the same time, network geometry is at the heart of quantum gravity, since many approaches to quantum gravity assume that space-time is discrete and network-like at the quantum level. In network geometry a crucial problem is the identifications of mechanisms to describe emergent network geometry. In this talk, after an introduction to complex network theory, I will present a class of non-“equilibrium models [1-4] in which geometrical properties of the networks emerge spontaneously from their dynamics. Specifically we will discuss the model called network geometry with flavor (NGF). The NGF can generate discrete geometries of different nature, ranging from chains and higher dimensional manifolds to scale-free complex networks. Interestingly the NGF with fitness of the nodes reveals relevant relations with quantum statistics. In fact the faces of the NGF have generalized degrees that follow either the Fermi-Dirac, Boltzmann or Bose-Einstein statistics depending on their flavor and on their dimensionality. Specifically, NGFs with flavor $s=-1$, when constructed in dimension $d=3$ gluing tetrahedra along their triangular faces, have the generalized degrees of the triangular faces, of the links, and of the nodes following respectively the Fermi-Dirac, the Boltzmann or the Bose-Einstein distribution.

Emergent geometry

**It is possible that
the hyperbolic geometry is an
emergent property
of the network evolution
which follows dynamical rules
that make no use of the hidden geometry?**

Growing networks describe the emergence of complexity

Would growing simplicial complexes
describe
the emergence of geometry?

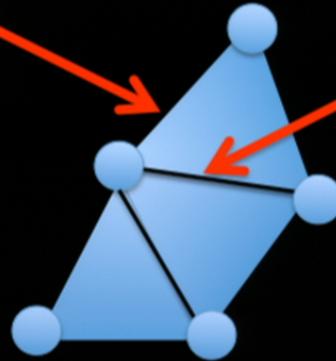

Emergent Network Geometry

The model describes the underlying structure of a simplicial complex constructed by gluing together triangles by a non-equilibrium dynamics.

**Every link is incident to
at most m triangles with $m > 1$.**

Saturated and Unsaturated links

Unsaturated link

Saturated link

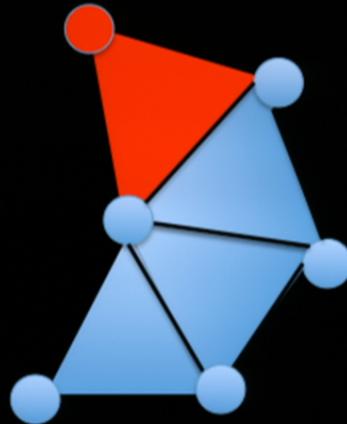

$m=2$

- if the link is unsaturated, i.e. less than m triangles are incident on it
- if the link is saturated, i.e. the number of incident triangles is given by m

Process (a)

We choose a unsaturated link and we glue a new triangle the link

Growing
Simplicial
Complex

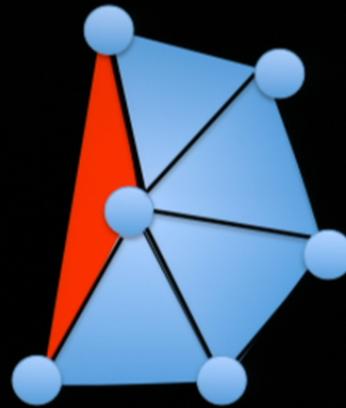

Growing
Geometrical
Network

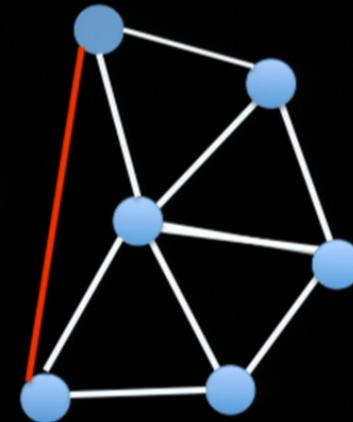

Process (b)

We choose two adjacent unsaturated links and we add the link between the nodes at distance 2 and all triangles that this link closes as long that this is allowed.

**Growing
Simplicial
Complex**

**Growing
Geometrical
Network**

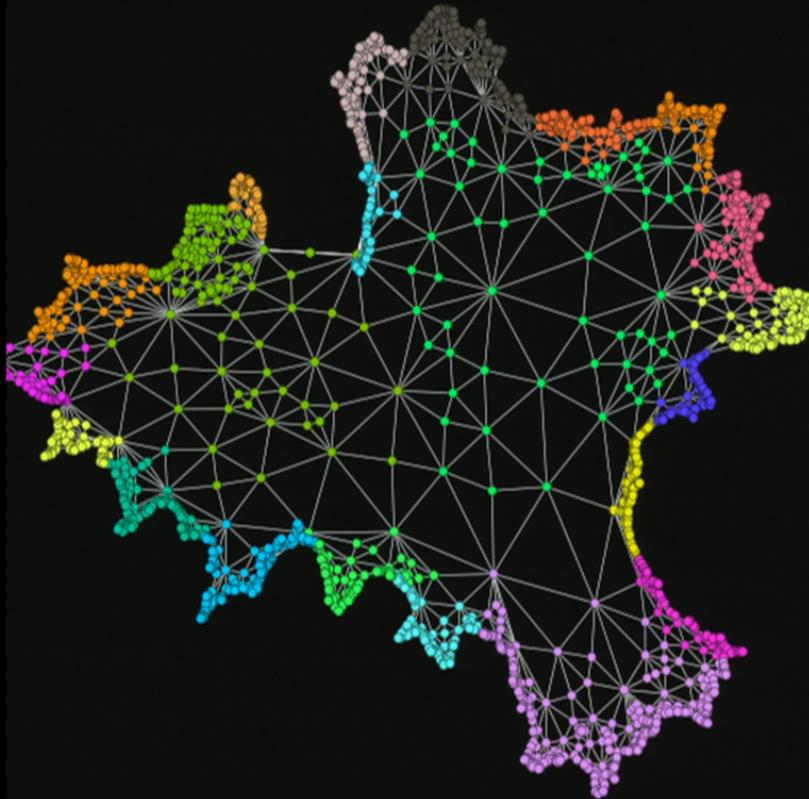

The model

Starting from an initial triangle,
At each time

- process (a) takes place and
- process (b) takes place with probability $p < 1$

Z. Wu, G. Menichetti, C. Rahmede, G. Bianconi, Scientific Reports 5, 10073 (2015)

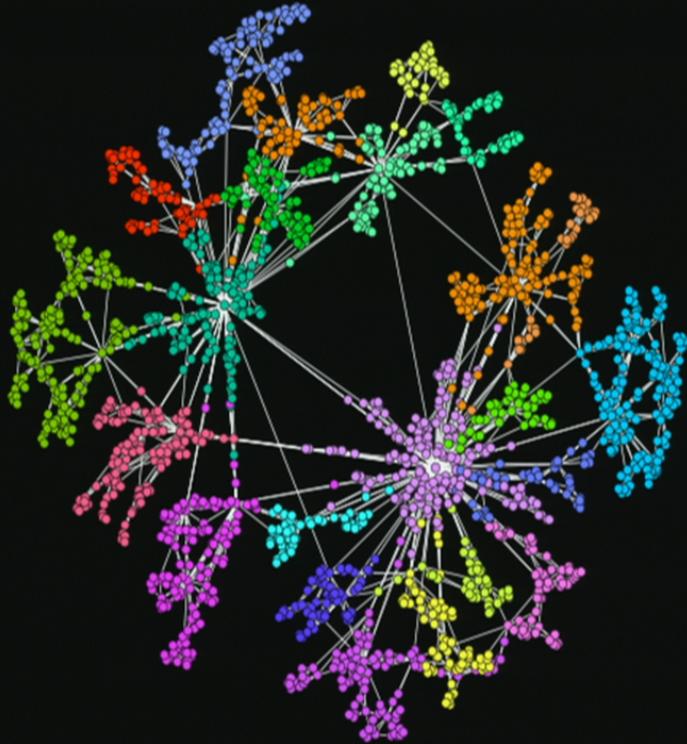

Discrete Manifolds

A discrete manifold of dimension $d=2$ is a simplicial complex formed by triangles such that every link is incident to at most two triangles.

Exponential degree distribution

Scale-free networks

For $m = \infty$ a **scale-free**, small-world network with high clustering coefficient and significant community structure is generated.

Degree distribution

- For $m=2$ and $p=0$ we can calculate the degree distribution given by

$$P(k) = \frac{1}{2} \left(\frac{2}{3} \right)^{k-1}$$

- For $m = \infty$ and $p=0$ we can calculate the degree distribution given by

$$P(k) = \frac{12}{(k+2)(k+1)k}$$

Combinatorial Curvature

The combinatorial curvature
for a node i of a planar triangulation is

$$R_i = 1 - \frac{k_i}{2} + \frac{T_i}{3}$$

- k_i is the degree of the node i , T_i is the number of triangles to which node i belongs

For a node in the bulk

$$R_i = \frac{6 - k_i}{6}$$

For a node at the surface

$$R_i = \frac{4 - k_i}{6}$$

Distribution of local curvature

$m=2$ $p=0.9$

Exponential network

$$\langle R \rangle = \frac{1}{N}$$
$$\langle R^2 \rangle < \infty$$

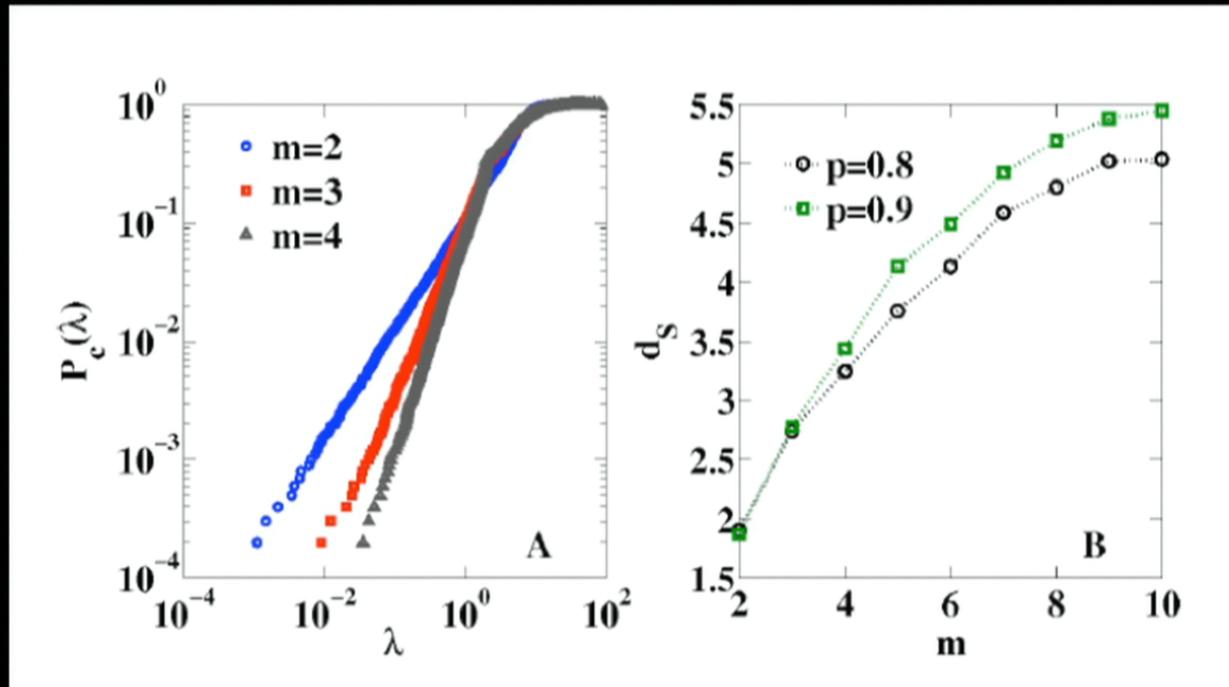

$m=\text{infinity}$ $p=0$

Scale-free network

$$\langle R \rangle = \frac{1}{N}$$
$$\langle R^2 \rangle = \infty$$

Finite spectral dimension

$$L_{ij} = k_i \delta_{ij} - a_{ij}$$

$$\rho(\lambda) \approx \lambda^{(d/2-1)}$$

$$P_c(\lambda) \approx \lambda^{d/2}$$

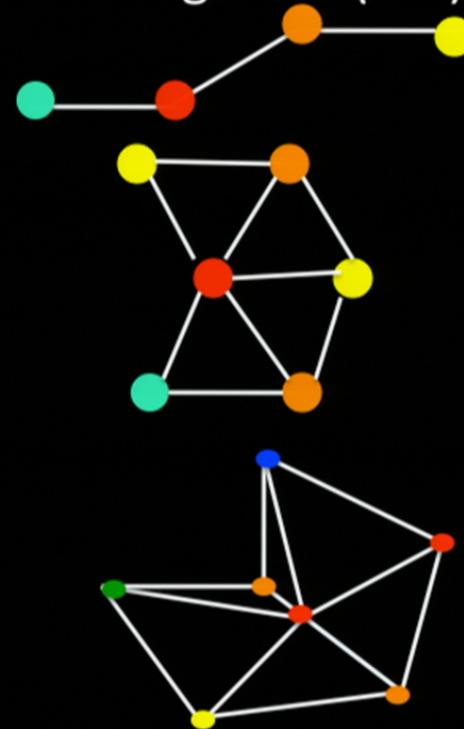

The d-dimensional simplicial complexes

In dimension d the growing simplicial complex built by gluing simplices of dimension d along their $(d-1)$ -face

In $d=1$ the simplices are links

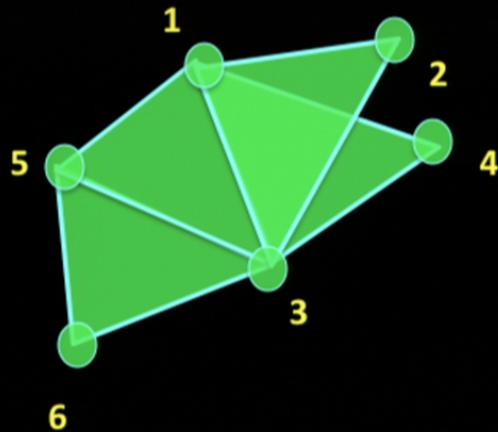

In $d=2$ the simplices are triangles

In $d=3$ they are tetrahedra.

Generalized degrees

The generalized degree $k_{d,\delta}(\alpha)$ of a δ -face α in a d -dimensional simplicial complex is given by the number of d -dimensional simplices incident to the δ -face α .

Number of triangles incident

- to the nodes $k_{2,0}$
- to the links $k_{2,1}$

i	$k_{2,0}(i)$	(i,j)	$k_{2,1}(i,j)$
1	3	(1,2)	1
2	1	(1,3)	3
3	4	(1,4)	1
4	1	(1,5)	1
5	2	(2,3)	1
6	1	(3,4)	1
		(3,5)	2
		(3,6)	1
		(5,6)	1

The incidence number

To each $(d-1)$ -face α we associate the incidence number

$$n_{\alpha} = k_{d,d-1}(\alpha) - 1$$

given by

the number of d -dimensional simplices incident to the face minus one

If n_{α} takes only values $n_{\alpha}=0,1$ the *simplicial complex is a discrete manifold.*

Network Geometry with Flavor

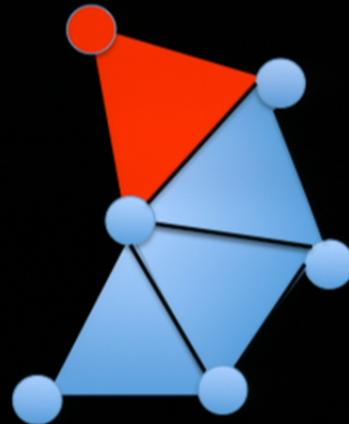

*We start with a d-dimensional simplex,
At each time we choose a (d-1)-face
with probability*

$$\Pi_{\alpha}^{[s]} = 1 + s n_{\alpha}$$

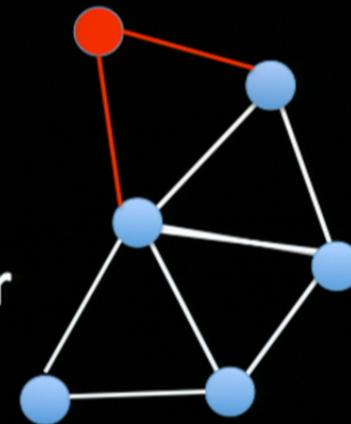

and we glue to it a new d-dimensional simplex

The flavor $s = -1, 0, 1$

**Growing
Simplicial**

**Network
Geometry
with Flavor**

Flavor $s=-1,0,1$ and attachment probability

$$\Pi_{\alpha}^{[s]} = \frac{(1 + s n_{\alpha})}{\sum_{\alpha' \in Q_{d,d-1}} (1 + s n_{\alpha'})} = \begin{cases} \frac{(1 - n_{\alpha})}{Z^{[-1]}} & s = -1 \\ \frac{1}{Z^{[0]}} & s = 0 \\ \frac{k_{d,d-1}(\alpha)}{Z^{[1]}} & s = 1 \end{cases}$$

$s=-1$ Manifold

$s=0$ Uniform attachment

$s=1$ Preferential attachment

$n_{\alpha}=0,1$

$n_{\alpha}=0,1,2,3,4\dots$

$n_{\alpha}=0,1,2,3,4\dots$

Exponential

Uniform attachment

$s=0$

Scale-free

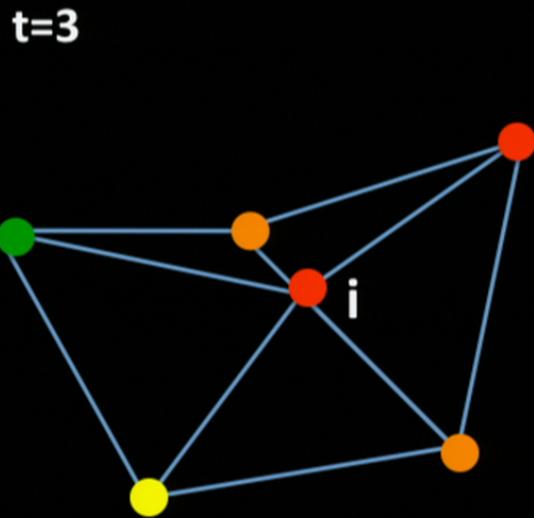

Preferential attachment

$s=1$

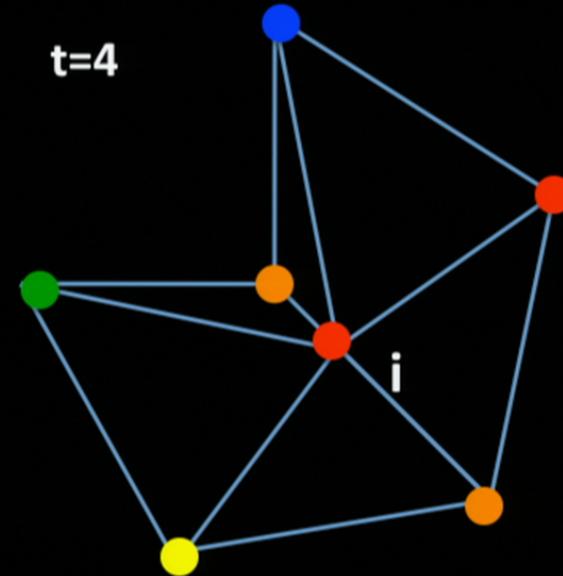

Scale-free

Effective preferential attachment emerging in $d=3$ dimensions

Node i has generalized degree 3

Node i is incident to 5 unsaturated faces

Node i has generalized degree 4

Node i is incident to 6 unsaturated faces

Degree distribution of NGF

- The NGF with $s+d=0$, i.e. with $(s,d)=(-1,1)$ are chains
- For $s+d=1$, i.e. $(s,d)=(-1,2)$ and $(0,1)$ we have

$$P_d^{[s]} = \left(\frac{d}{d+1} \right)^{k-d} \frac{1}{d+1}$$

- For $s+d>1$ we have

$$P_d^{[s]} = \frac{d+s}{2s+s} \frac{\Gamma[1+(2d+s)/(d+s-1)]}{\Gamma[d/(d+s-1)]} \frac{\Gamma[k-d+d/(d+s-1)]}{\Gamma[k-d+1+(2d+s)/(d+s-1)]}$$

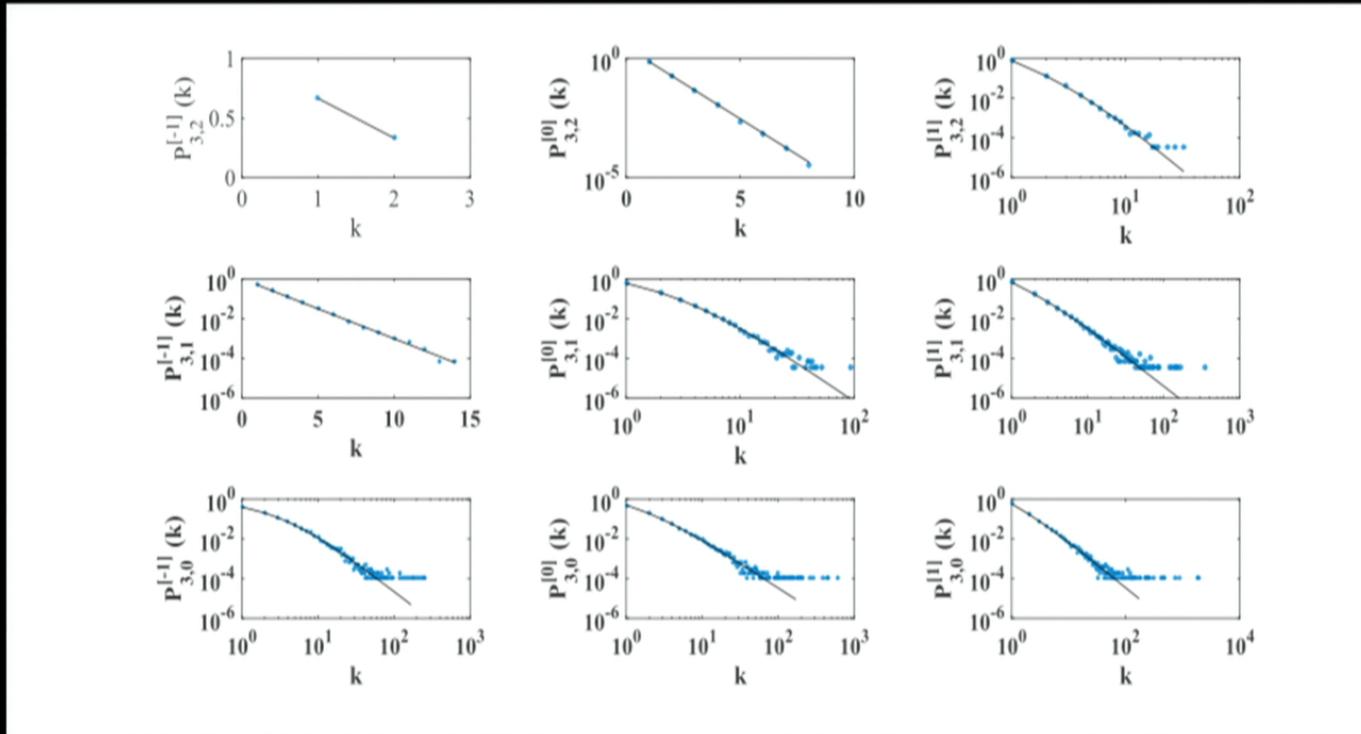

Generalized degree distribution for Network Geometry with Flavor (NGF)

flavor	$s = -1$	$s = 0$	$s = 1$
$\delta = d - 1$	Binomial	Exponential	Power-law
$\delta = d - 2$	Exponential	Power-law	Power-law
$\delta \leq d - 3$	Power-law	Power-law	Power-law

- For $s=1$ the NGF are always scale-free
- For $s=0$ the NGF are scale-free for $d>1$
- For $s=-1$ the NGF are scale-free for $d>2$

G. Bianconi, C. Rahmede, Scientific Reports (2015);PRE (2016).

Generalized degree distributions of NGF

Theory versus simulation in NGF $s=-1,0,1$ and $d=3$

Hausdorff dimension and Area

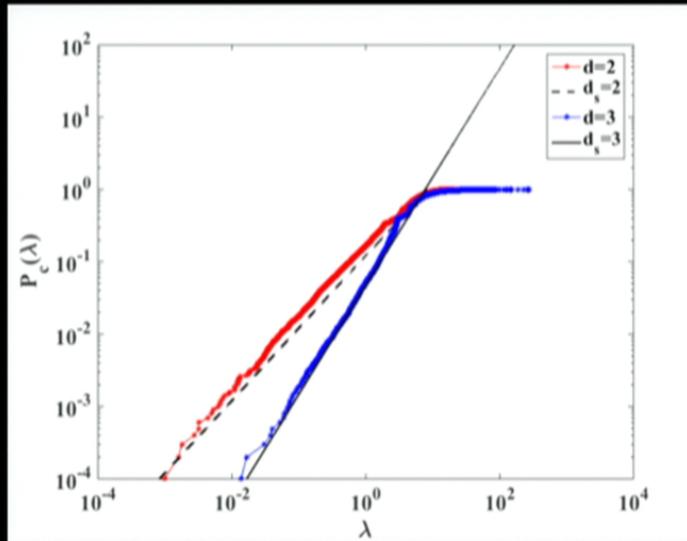

The NGF have Hausdorff dimension

$$d_H = \infty$$

The Area A of the NGFs is
the number of $(d-1)$ -faces with $n_\alpha=0$
we have

$$A \propto N$$

The Spectral dimensions of NGF with $s=-1$ is equal to the dimension of the simplex

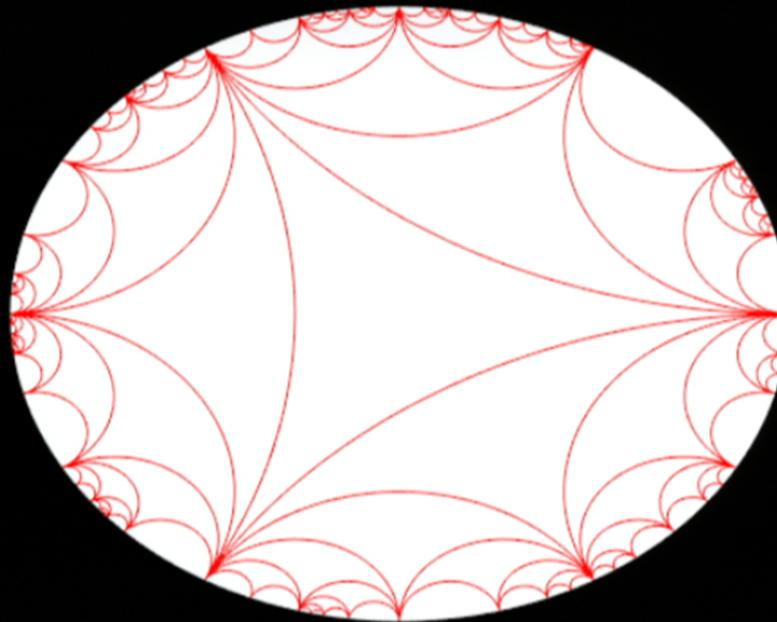

$$L_{ij} = k_i \delta_{ij} - a_{ij}$$

$$\rho(\lambda) \approx \lambda^{d_s/2-1}$$

$$P_c(\lambda) \approx \lambda^{d_s/2}$$

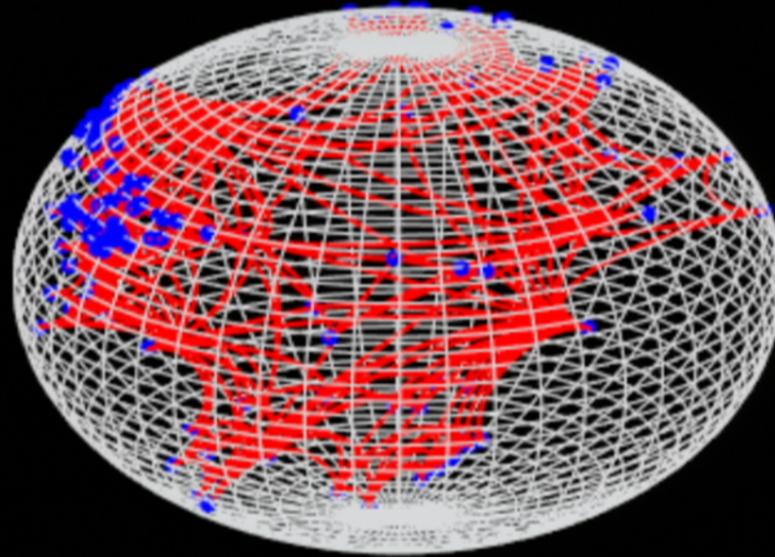

Emergent hyperbolic geometry

The emergent hidden geometry is the hyperbolic H^d space
Here all the links have equal length

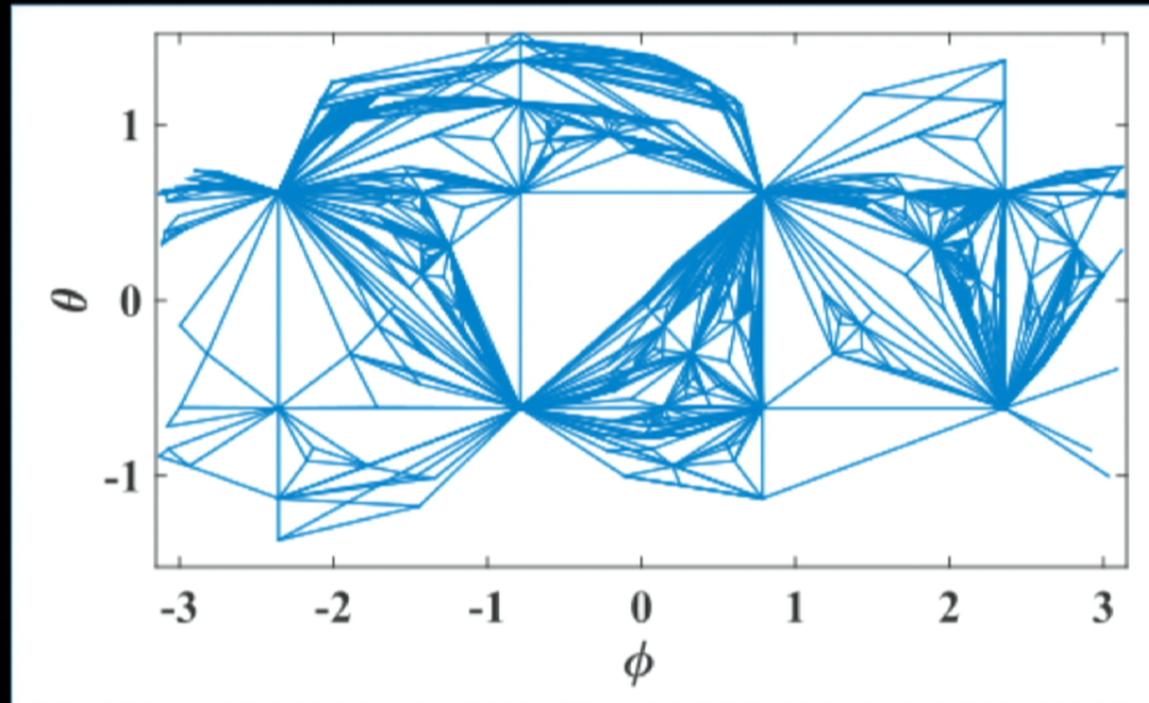

d=2

Emergent hyperbolic geometry

d=3

The pseudo-fractal geometry of the surface of the 3d manifold (random Apollonian network)

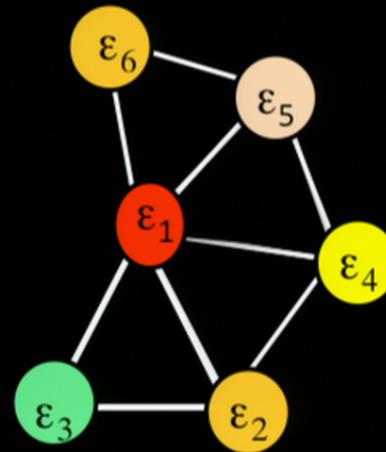

Energies of the nodes

Not all the nodes are the
same!

Let assign to each node i

an energy ε from a

$g(\varepsilon)$ distribution

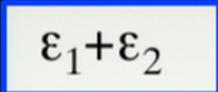

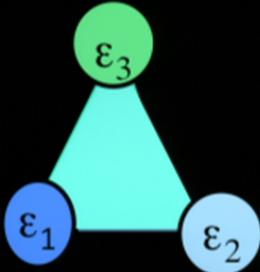

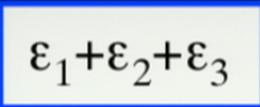

Energy of the δ -faces

Every δ -face α is associated to an energy which is the sum of the energy of the nodes belonging to α

$$\varepsilon_\alpha = \sum_{i \in \alpha} \varepsilon_i$$

For example, in $d=3$

the energy of a link  is 

the energy of a face  is 

Fitness of the δ -faces

The fitness of a δ -face α is given by

$$\eta_{\alpha} = e^{-\beta \varepsilon_{\alpha}}$$

where $\beta=1/T$ is the **inverse temperature**

If $\beta=0$ all the nodes have same fitness
If $\beta \gg 1$ small differences in energy have large impact on
the fitness of the faces

Network Geometry with Flavor

Starting from a d-dimensional simplex
We choose a (d-1)-dimensional face α ,
with probability

$$\Pi_{\alpha} = \frac{e^{-\beta \varepsilon_{\alpha}} (1 + s n_{\alpha})}{\sum_{\alpha' \in Q_{d,d-1}} e^{-\beta \varepsilon_{\alpha'}} (1 + s n_{\alpha'})}$$

and glue a new d-dimensional simplex to it.

The parameter $\beta=1/T$ is the **inverse temperature**.

If $\beta=0$ we are recast into the previous model

The **flavor** $s=-1,0,1$

Statistical mechanics of the manifold evolution

Each manifold evolution is characterized by the sequence

$$\{\alpha(t')\}_{t' \leq t}$$

of (d-1)-faces chosen for growing the manifold

Each network history up to time $t=N$ has probability

$$P\left(\{\alpha(t')\}_{t' \leq t} \mid \{\varepsilon(t')\}_{t' \leq t}\right) = \frac{e^{-\beta E}}{\tilde{Z}(t)} = \frac{e^{-\beta(E - \mu N)}}{N!}$$

where the total energy E associated to the manifold is given by

$$E = \sum_{\alpha \in Q_{d,d-1}} \varepsilon_{\alpha} n_{\alpha}$$

Generalized Area law

Each given network G is obtained at time t with probability

$$P\left(G\left|\left\{\varepsilon_i\right\}_{i\leq N}\right.\right) = e^{-\beta(E-v N)}$$

Where this expression is obtained from the probability of each single history summing over all the histories resulting in the same network G
The change in entropy of the network satisfies

$$\Delta S = \beta(\langle \Delta E \rangle - v \Delta N) = [\beta(\langle e \rangle) - v] \Delta N \propto [\beta(\langle e \rangle) - v] \Delta A$$

because $N=V$ is proportional to the area A of the manifold.

Generalized Area law

Each given network G is obtained at time t with probability

$$P\left(G\left|\left\{\varepsilon_i\right\}_{i\leq N}\right.\right) = e^{-\beta(E-v N)}$$

Where this expression is obtained from the probability of each single history summing over all the histories resulting in the same network G
The change in entropy of the network satisfies

$$\Delta S = \beta(\langle \Delta E \rangle - v \Delta N) = [\beta(\langle e \rangle) - v] \Delta N \propto [\beta(\langle e \rangle) - v] \Delta A$$

because $N=V$ is proportional to the area A of the manifold.

Energy of manifolds and Regge curvature

Assuming that the simplices are flat the Regge curvature R_α of a $(d-2)$ -face α is given by

$$R_\alpha = \pi - \theta_d k_{d,d-2}(\alpha)$$

The energy E can be expressed in term of the curvature as

$$E = \sum_{\alpha \in S_{d,d-1}} \varepsilon_\alpha n_\alpha = -\frac{B_d}{\theta_d} \left(\sum_{\alpha \in S_{d,d-2}} \varepsilon_\alpha R_\alpha - \Lambda \right)$$
$$\Lambda = \left(\pi - \frac{\theta_d}{2} \right) \sum_{\alpha \in S_{d,d-2}} \varepsilon_\alpha$$

Bianconi-Barabasi model or the fitness model

Is the NGF $d=1$ $s=1$

$$\Pi_i^{[-1]} = \frac{e^{-\beta \varepsilon_i} k_i}{\sum_{j=1, N} e^{-\beta \varepsilon_j} k_j}$$

The average degree of the nodes with energy ε follows the Bose-Einstein statistics

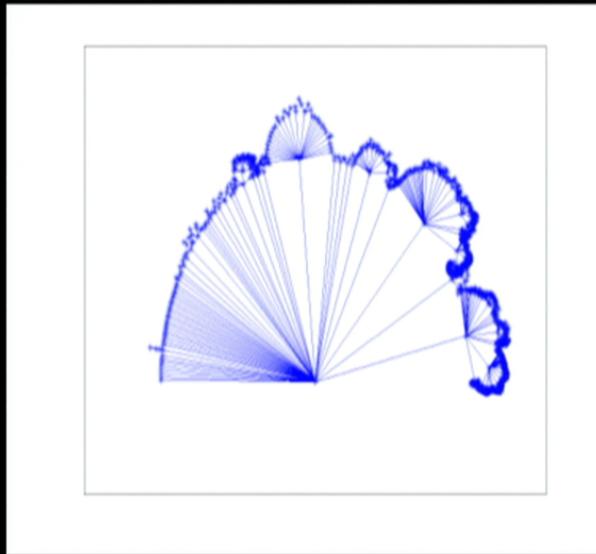

$$\langle [k_i - 1] | \varepsilon \rangle = \frac{1}{e^{\beta(\varepsilon - \mu)} - 1}$$

G. Bianconi A.L. Barabasi PRL (2001)

Bose-Einstein condensation in complex networks

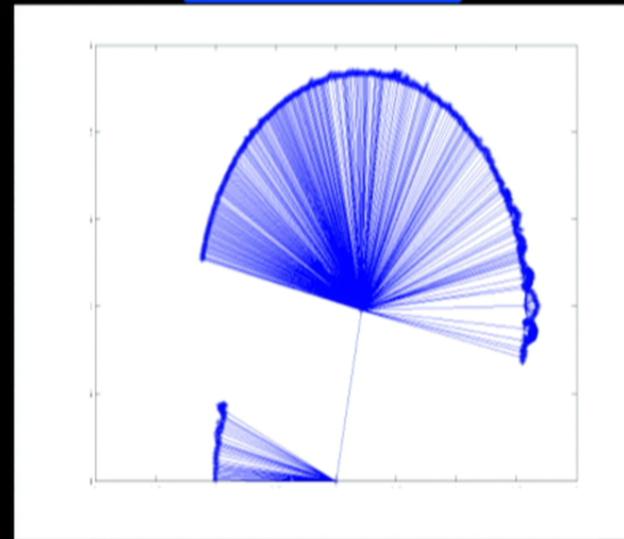

Scale-Free phase

$$\beta < \beta_c$$

Bose-Einstein condensate phase

$$\beta > \beta_c$$

Quantum statistics and Network Geometry with Flavor

**What is the combined effect
of flavor and dimensionality
on the emergence of
quantum statistics?**

The average of the generalized degree of the NGF over δ -faces of energy ε

$$\langle [k_{d,\delta} - 1] | \varepsilon \rangle$$

follows

flavor	$s = -1$	$s = 0$	$s = 1$
$\delta = d - 1$	Fermi-Dirac	Boltzmann	Bose-Einstein
$\delta = d - 2$	Boltzmann	Bose-Einstein	Bose-Einstein
$\delta \leq d - 3$	Bose-Einstein	Bose-Einstein	Bose-Einstein

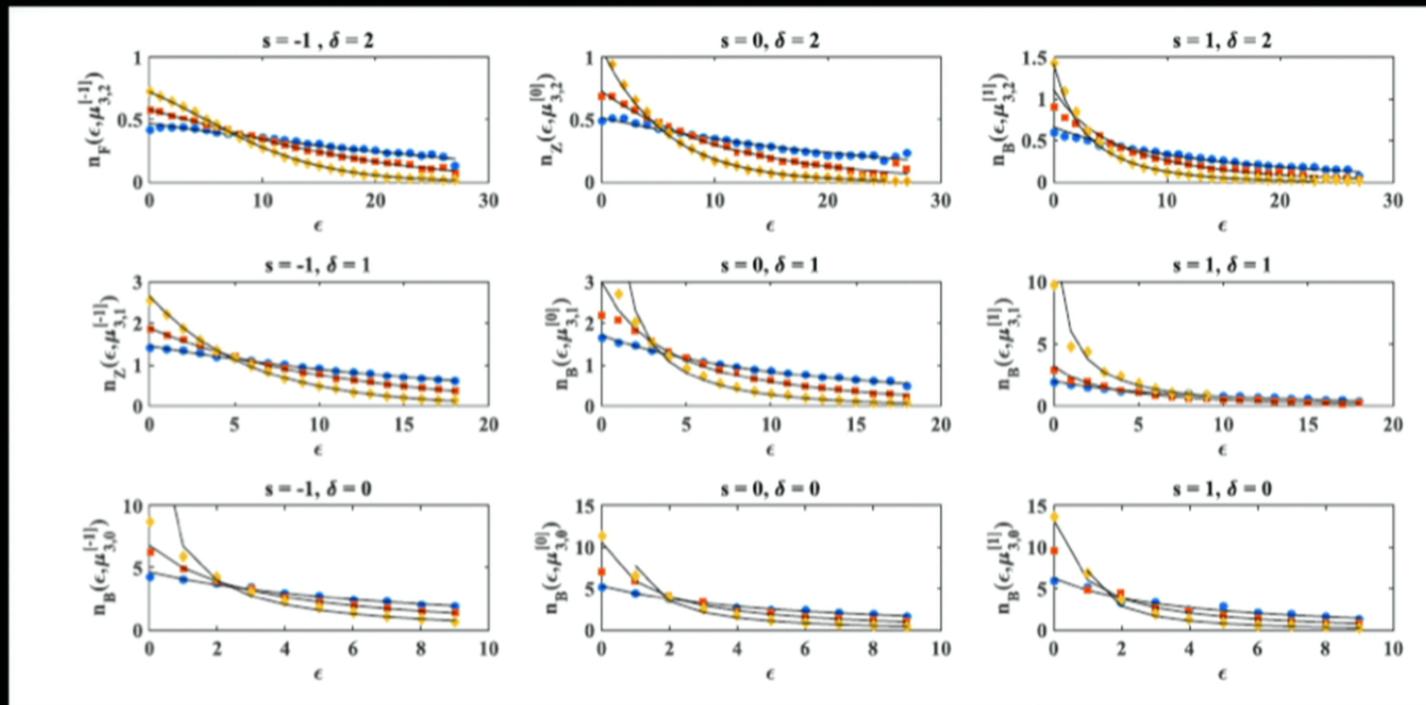

G. Bianconi, C. Rahmede, Scientific Reports (2015);PRE (2016).

Manifolds in $d=3$

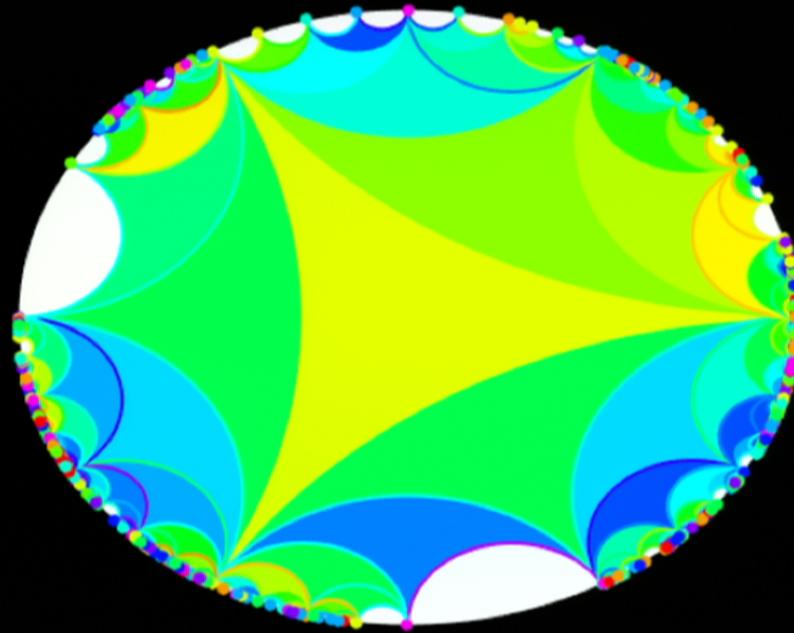

*In NGF with $s=-1$ and $d=3$
also called*

*Complex Quantum Network Manifolds
the average of the generalized degree follow

distribution
respectively for
triangular faces, links and nodes*

Theory and simulations for NGF in $d=3$

Emergent geometry at high temperature

$d=2$
 $\beta=0.01$

Conclusions

*Growing simplicial complexes called Network Geometry with Flavor (NGF)
display:*

- **Non-trivial distribution of the curvature**
- ***strong dependence on the dimensionality***
 - *NGF with $s=-1$ are manifolds and are scale-free for $d>2$*
 - *NGF with $s=0$ (uniform attachment) are scale-free for $d>1$*
- ***emergent hyperbolic geometry***

NGF at finite temperature (with fitness and energy)

- *have generalized degrees following the Fermi-Dirac, Boltzmann or Bose-Einstein distribution depending on the dimensionality of the δ -face and the flavor s .*
- *NGF can undergo phase transition strongly affecting their hidden hyperbolic geometry.*
