Title: GEOMETRY OF QUANTUM ENTANGLEMENT

Date: Dec 01, 2016 03:30 PM

URL: http://pirsa.org/16120010

Abstract: A geometric approach to investigation of quantum entanglement is advocated.

We discuss first the geometry of the (N^2-1)--dimensional convex body

of mixed quantum states acting on an N--dimensional Hilbert space

of this set into 2- and 3-dimensional spaces.

For composed dimensions, N=K^2, one consideres the subset

of separable states and shows that it has a positive measure.

Analyzing its properties contributes to our understanding of

of y>
quantum entanglement and its time evolution.

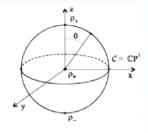

Pirsa: 16120010 Page 1/53

Pure states in a finite dimensional Hilbert space \mathcal{H}_N

Qubit = quantum bit; N=2, $\langle\psi|\psi
angle=1$, $|\psi
angle\sim e^{ilpha}|\psi
angle$

$$|\psi\rangle = \cos\frac{\vartheta}{2}|1\rangle + e^{i\phi}\sin\frac{\vartheta}{2}|0\rangle$$

Bloch sphere of N = 2 pure states

Space of pure states for an arbitrary N:

a complex projective space $\mathbb{C}P^{N-1}$ of 2N-2 real dimensions.

Unitary evolution

Fubini-Study distance in $\mathbb{C}P^{N-1}$

$$D_{FS}(|\psi\rangle, |\varphi\rangle) := \arccos |\langle \psi | \varphi \rangle|$$

Unitary evolution

Let $U=\exp(iHt)$. Then $|\psi'\rangle=U|\psi\rangle$. Since $|\langle\psi|\varphi\rangle|^2=|\langle\psi|U^\dagger U|\varphi\rangle|^2$ any unitary evolution is an **isometry** (with respect to any standard distance !)

Quantum Chaos: what happends for large N?

How an **isometry** may lead to a classically chaotic dynamics? The limits $t \to \infty$ and $N \to \infty$ do not commute.

Mixed quantum states

Set \mathcal{M}_N of all mixed states of size N

$$\mathcal{M}_{N} := \{ \rho : \mathcal{H}_{N} \to \mathcal{H}_{N}; \rho = \rho^{\dagger}, \rho \geq 0, \operatorname{Tr} \rho = 1 \}$$

Example: N=2, **One–qubit** states: Bloch sphere + its interior, $\mathcal{M}_2=\mathcal{B}_3\subset\mathbb{R}^3$ - Bloch ball with all pure states at the boundary

The set \mathcal{M}_N is compact and convex:

 $\rho = \sum_{i} a_{i} |\psi_{i}\rangle \langle \psi_{i}| \text{ where } a_{i} \geq 0 \text{ and } \sum_{i} a_{i} = 1.$ It has $N^{2} - 1$ real dimensions, $\mathcal{M}_{N} \subset \mathbb{R}^{N^{2} - 1}$.

What the set of all N = 3 mixed states looks like?

An 8 dimensional convex set with only 4 dimensional subset of pure (extremal) states, which belong to its 7 dim boundary

Operator theory: Numerical Range (Field of Values)

Definition

For any operator A acting on \mathcal{H}_N one defines its **NUMERICAL RANGE** (Wertevorrat) as a subset of the complex plane defined by:

$$\Lambda(A) = \{ \langle x | A | x \rangle : | x \rangle \in \mathcal{H}^N, \ \langle x | x \rangle = 1 \}. \tag{1}$$

Hermitian case

For any hermitian operator $A = A^{\dagger}$ with spectrum $\lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_N$ its **numerical range** forms an interval: the set of all possible expectation values of the observable A among arbitrary pure states, $\Lambda(A) = [\lambda_1, \lambda_N]$.

$$N=4 \xrightarrow{\lambda_1 \quad \lambda_2 \quad \lambda_3 \quad \lambda_4} \longrightarrow$$

Pirsa: 16120010 Page 16/53

Numerical range and its properties

Compactness

 $\Lambda(A)$ is a **compact** subset of \mathbb{C} .

Convexity: Hausdorf-Toeplitz theorem

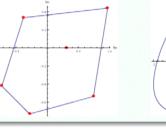

- $\Lambda(A)$ is a **convex** subset of \mathbb{C} .

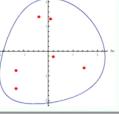

Example

Numerical range for random matrices of order ${\it N}=6$

Quantum States and Numerical Range/Shadow

Classical States & normal matrices

Proposition 1.Let C_N denote the set of classical states of size N, which forms the regular simplex Δ_{N-1} in \mathbb{R}^{N-1} . Then the set of similar images of orthogonal projections of C_N on a 2-plane is equivalent to the set of all possible numerical ranges $\Lambda(A)$ of all normal matrices A of order N (such that $AA^* = A^*A$).

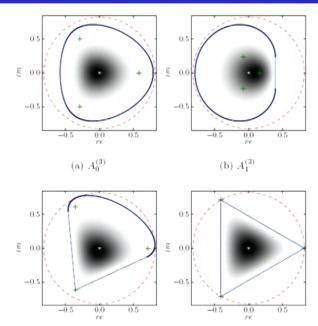

Quantum States & non-normal matrices

Proposition 2.Let \mathcal{M}_N denotes the set of quantum states size N embedded in \mathbb{R}^{N^2-1} with respect to Euclidean geometry induced by Hilbert-Schmidt distance. Then the set of similar images of orthogonal projections \mathcal{M}_N on a 2-plane is equivalent to the set of all possible numerical ranges $\Lambda(A)$ of all matrices A of order N.

28 / 52

Pirsa: 16120010 Page 27/53

Numerical range for matrices of order N = 3.

Classification by **Keeler, Rodman, Spitkovsky 1997** Numerical range Λ of a 3×3 matrix A forms:

- a) $\Lambda(A)$ is a compact set of an 'ovular' shape (which contains three eigenvalues!) the **generic** case, s=0
- **b)** a compact set with **one** flat part (e.g. convex hull of a **cardioid**), s = 1
- c) a compact set with **two** flat parts (e.g. convex hull of an ellipse and a point outside it), s = 2
- d) triangle of eigenvalues, $\Lambda(A) = \Delta(\lambda_1, \lambda_2, \lambda_3)$ for any **normal matrix** A one has s = 3

These four cases describe the shape of possible projections of the 8D set \mathcal{M}_3 of mixed quantum states of size N=3 onto a 2-plane.

Joint Numerical Range & Quantum States

Joint Numerical Range (JNR) of a set of m operators

 $\Lambda(A_1, A_2, \ldots, A_m) = (\langle \psi | A_1 | \psi \rangle, \langle \psi | A_2 | \psi \rangle, \ldots, \langle \psi | A_m | \psi \rangle) \subset \mathbb{R}^m.$

For $m \ge N^2 - 1$ JNR is (in general) **not** a **convex set**!

Set m=2, decompose $A=A_H+iA_A$ into its **Hermitian** and **anti–Hermitian** part. Then $\Lambda(A)=\Lambda(A_H,A_A)$

Proposition 3. Take a set $\{A_1, \ldots, A_{N^2-1}\}$ of matrices of size N forming an **orthonormal basis** in the space of Hermitian, traceless matrices. Then

- $\Lambda(A_1, A_2, ..., A_{N^2-1})$ is affine isomorphic to the set $\Omega_N = \mathbb{C}P^{N-1}$ of pure quantum states of size N (embedded in \mathbb{R}^{N^2-1}),
- The convex hull of $\Lambda(A_1, A_2, \dots, A_{N^2-1})$ is isomorphic to the set \mathcal{M}_N of mixed quantum states of size N.
- $\Lambda(A_1,A_2,\ldots,A_m)$ with $m\leq N^2-1$ forms a projection of Ω_N into \mathbb{R}^m .

Joint Numerical Range: some examples

N=2: one qubit states

Let $\sigma_1, \sigma_2, \sigma_3$ denote three trace-less **Pauli matrices** of size N=2. Then

- $\Lambda(\sigma_1, \sigma_2, \sigma_3) = \Omega_2 = \mathbb{C}P^1$ forms the **Bloch sphere** S^2 of all one–qubit pure states.
- The **convex hull** of $\Lambda(\sigma_1, \sigma_2, \sigma_3)$ forms the **Bloch ball**, $\mathcal{M}_2 = B_3 \subset \mathbb{R}^3$ of all one–qubit mixed states.

N=3: one qutrit states

Let $\lambda_1, \ldots \lambda_8$ denote eight traceless **Gell–Man matrices** of size 3: the generators of SU(3).

Then

- $\Lambda(\lambda_1, \dots \lambda_8) = \Omega_3 = \mathbb{C}P^2$ forms the set of all one–qutrit pure states.
- The **convex hull** of $\Lambda(\lambda_1, \ldots, \lambda_8)$ forms the set of N=3 mixed states a convex body \mathcal{M}_3 embedded in \mathbb{R}^8

Concluding Remarks

- The set \mathcal{M}_N of **mixed quantum states** of size N forms a scene for which the screenplays of **quantum information** processing are written.
 - It is useful for any author to learn about the **structure & geometry** of the scene.
- As the set \mathcal{M}_N has N^2-1 dimensions for $N\geq 3$ it is possible to investigate it by studying the **numerical range**: its projections onto a 2- or 3- planes.
- **Geometric approach** is usefull to study **quantum entanglement** and its dynamics. It allows one to explain the effects of entanglement revival and entanglement sudden death.
- More work is still required to understand the consequences of noise and decoherence for known schemes of **quantum computation**.
