

Title: From 3D TQFTs to 4D models with defects

Date: Aug 04, 2017 11:00 AM

URL: <http://pirsa.org/17080004>

Abstract: I will explain a general strategy to lift (2+1)D topological phases, in particular string nets, to (3+1)D models with line defects. This allows a systematic construction of (3+1)D topological theories with defects, including an improved version of the Walker-Wang Model. It has also an interesting application to quantum gravity as it leads to quantum geometry realizations for which all geometric operators have discrete and bounded spectra. I will furthermore comment on some interesting (self-) duality relations that emerge in these constructions.

# Lifting $(2+1)$ TQFTs to $(3+1)$ theories with line defects

Kitaev model, string nets,  
Hopf algebra gauge theory, ...

(3+1)D theory

?

# Motivation

(2+1)D TQFT's

Kitaev model, string nets,  
Hopf algebra gauge theory, ...

Hilbert space (code space),  
Operators

(3+1)D theory

(3+1) TQFTs with line defects  
eg. improved Walker-Wang, generalizations

Hilbert space (code space),  
Operators

In particular: braiding needs 2D surfaces. How to (conveniently) implement it in (3+1)D?

In addition: number of reasons from quantum gravity.

A new quantum geometry realization:

Hilbert spaces are finite, all observables have discrete spectra, new gauge invariant bases.

# Strategy: from (2+1)D TQFT to a (3+1)D theory with line defects

[Delcamp, BD: JMP 2017]

(2+1)D TQFT

assigns degrees of freedom  
to non-contractible curves  
on a surface

(3+1)D TQFT: 3-sphere with  
one-skeleton of (tetrahedral)  
triangulation removed

curves around triangles  
are contractible in  
3-sphere

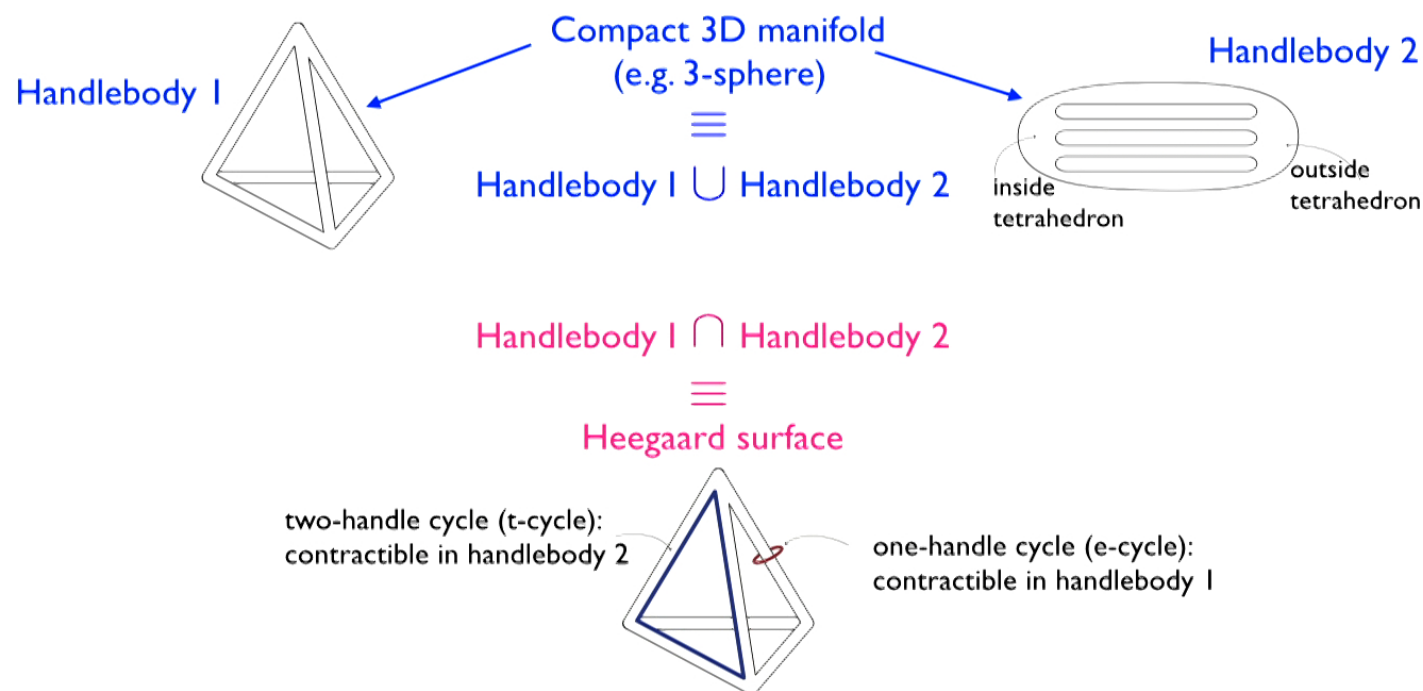

curves around the  
edges of the  
triangulation are  
not contractible

want to assign degrees of  
freedom  
to curves around edges of  
triangulation

Use (2+1) D theory to assign state space to a 3D triangulation.  
But impose (contractibility/ flatness) constraints associated to curves  
around triangles.

# Heegaard splitting and diagrams

A Heegaard diagram is a Heegaard surface decorated with generating basis of one-handle cycles and two-handle cycles.

Heegaard diagrams encode uniquely topology of 3D manifold.

# Heegaard diagrams

Heegaard diagrams can be constructed from a triangulation of the 3D manifold.

Set of cycles around triangles generates (over-completely) all curves that are contractible even if we do take out the one-skeleton of the triangulation.

Thus it is sufficient to impose flatness constraints for the cycles around the triangles.

## Part II: Examples

# Strategy

1. Hilbert space, operators and bases for a closed surface.
2. Apply this to a Heegaard surface.
3. Impose constraints for 2-handle cycles and find operators and bases consistent with these constraints.

# BF theory / Kitaev model

string nets with non-modular fusion category  $\text{Rep}(G)$

# BF theory / Kitaev model

string nets with non-modular fusion category  $\text{Rep}(G)$

Hilbert space:

gauge invariant wave functions of flat  $G$ -connection

$$\delta_e(g_1 g_2 g_1^{-1} g_2^{-1}) \psi_{\text{inv}}(g_1, g_2)$$

A basis?

# BF theory / Kitaev model

string nets with non-modular fusion category

(2+1)D Hilbert space:  
gauge invariant wave functions of flat G-connection

(maximal commuting set of) Operators:  
projective Ribbon operators labeled by representations  
of Drinfel'd double of G  
 $\rho = (C, R)$

↑  
R: (electric) flux  
component

→  
C: magnetic/ connection  
component

# BF theory / Kitaev model

string nets with non-modular fusion category  $\text{Rep}(G)$

Hilbert space:

gauge invariant wave functions of flat  $G$ -connection

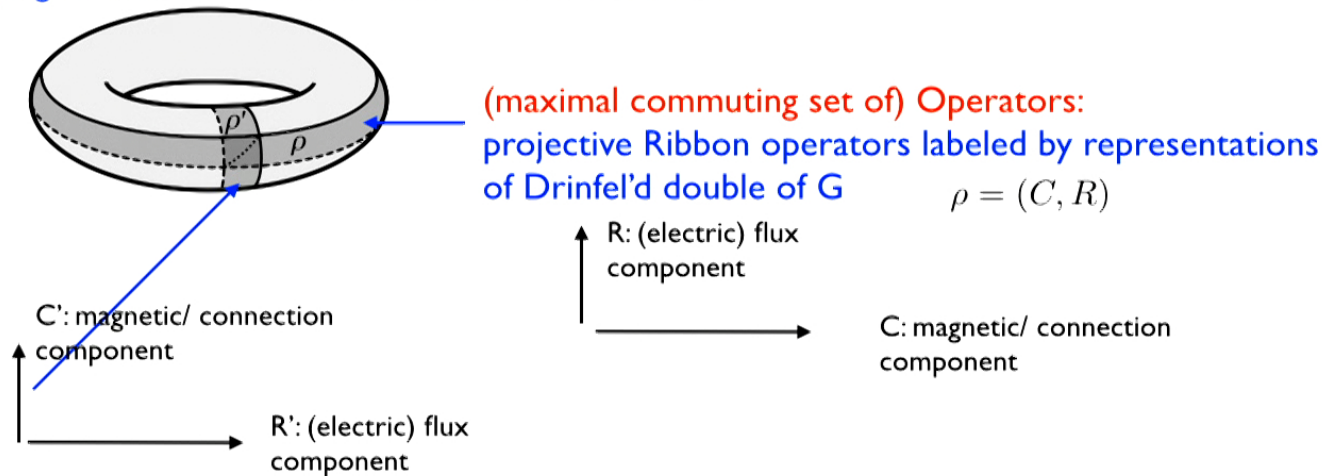

$$\delta_e(g_1 g_2 g_1^{-1} g_2^{-1}) \psi_{\text{inv}}(g_1, g_2)$$

A basis?

# BF theory / Kitaev model

string nets with non-modular fusion category

(2+1)D Hilbert space:  
gauge invariant wave functions of flat G-connection

Transformation between basis:

S-matrix:  $S_{\rho, \rho'}$

# Interpreted as (3+1)D state space

Impose constraint or projector:

$\rho$ -basis:  $C = \text{triv}$ ,  $R = \text{irrep of group } G$

spin network basis

$\rho'$ -basis:  $C = \text{arbitrary}$ , sum over  $R$

curvature basis:

new gauge invariant basis

(gauge invariant)  
group  
Fourier-transform  
from S-matrix

# Lifting $(2+1)D$ to $(3+1)D$

[Delcamp, BD: JMP 2017]

$(2+1)D$	$(3+1)D$
Fusion basis adjusted to (thickened) triangulation	curvature basis (for 3-sphere)
Fusion basis adjusted to (thickened) dual graph	spin network basis
General fusion basis on Heegard surface	general basis
Ribbon operators along e-cycles	(magnetic) Wilson loop
Ribbon operators along t-cycles	(electric) surface (t'Hooft) operator

Fourier-  
transform  
from S-matrix

# Generalizations

- line defects along triangulation and
- line defects along dual graph

allow degrees of freedom  
associated to triangles/  
edges of dual graph

weaken triangle constraints /  
projectors

$$\delta_e(h_t) \rightarrow \delta_N(h_t)$$

N: normal subgroup of G

e-cycle measures curvature/  
magnetic dof associated to edges

- line defects along triangulation and
- line defects along dual graph

'interaction': (3+1) interpretation?

(2+1)D Turaev-Viro 'code space'/  
string nets with modular fusion category  $\mathcal{C}$

## What to expect?

(maximal commuting set of) Operators:  
Projective ribbon operators labeled by objects  
of Drinfel'd centre of  $C$ :  $C \boxtimes C^{op}$

$$\rho = (j_o, j_u)$$

Impose constraint or projector:

trivializes **one of the copies** of the double

- (q-deformed) spin network basis: definition of Walker-Wang model
- curvature basis: diagonalizes Walker-Wang Hamiltonian

Basis for TV -TQFT

projector

Basis for WRT -TQFT

Quantization of Chern-Simon theory.

classical phase space:

quantum deformed (3+1) lattice Yang Mills = (2+1) Chern-Simons on Heegard surface

[Frolov; Riello]

# Hilbert space for (2+1)D Turaev-Viro TQFT

here: for surfaces without punctures

[Levin, Wen; Koenig, Kuperberg, Reichardt; Kirillov; BD, Geiller]

Kinematical (but gauge invariant) Hilbert space:

States based on spin-labelled three-valent graphs with  $SU(2)_k$  coupling rules imposed on the nodes.

Admissible spins:  $j = 0, \frac{1}{2}, 1, \dots, \frac{k}{2}$       labelling undirected edges of the graph.

Coupling rules:  $i \leq j + k, \quad j \leq i + k, \quad k \leq i + j, \quad i + j + k \in \mathbb{N}, \quad i + j + k \leq k$

# Hilbert space for (2+1)D Turaev-Viro TQFT

Physical Hilbert space - impose 'flatness' constraints:

Flatness constraints are imposed as equivalence relations between graph states:

Strands can be (isotopically) deformed.

$$j \text{ ————— } = j \text{ ~~~~~~ }$$

Strands with trivial spin can be omitted.

$$\begin{array}{c} 0 \\ | \\ j \text{ — } \text{---} \text{---} j \end{array} = j \text{ ————— }$$

2-2 Pachner move. Involving the F-symbol.

$$\begin{array}{c} i \text{ — } \text{---} \text{---} l \\ \diagdown \quad \diagup \\ m \text{ — } \text{---} \text{---} k \\ \diagup \quad \diagdown \\ j \end{array} = \sum_n F_{kln}^{ijm} \begin{array}{c} i \text{ — } \text{---} \text{---} l \\ \diagdown \quad \diagup \\ n \text{ — } \text{---} \text{---} k \\ \diagup \quad \diagdown \\ j \end{array}$$

3-1 Pachner move. Involving the F-symbol.

$$\begin{array}{c} i \text{ — } \text{---} \text{---} j \\ \diagdown \quad \diagup \\ m \text{ — } \text{---} \text{---} n \\ \diagup \quad \diagdown \\ k \end{array} = \frac{v_m v_n}{v_k} F_{nml}^{ijk} \begin{array}{c} i \text{ — } \text{---} \text{---} j \\ \diagdown \quad \diagup \\ k \end{array}$$

$$v_j = (-1)^j \sqrt{d_j}$$

Rather involved now:

Finding a basis of independent states and operators consistent with equivalence relations.

We need a) braiding and b) vacuum strands to define these.

## a) Braiding

Strands can cross each other. Such crossings can be resolved using the R-matrix of  $SU(2)_k$ .

$$\begin{array}{c} j \\ | \\ i \text{ --- } | \\ | \\ j \end{array} = \sum_k \frac{v_k}{v_i v_j} R_k^{ij} \begin{array}{c} j \\ | \\ i \text{ --- } | \\ | \\ j \end{array} \quad \begin{array}{c} j \\ | \\ i \text{ --- } | \\ | \\ j \end{array} = \sum_k \frac{v_k}{v_i v_j} (R_k^{ij})^* \begin{array}{c} j \\ | \\ i \text{ --- } | \\ | \\ j \end{array}$$

We can thus define the so-called **s-matrix** as the evaluation of the Hopf link.

(Planar graphs are equivalent to a number times the empty graph. This number is called the evaluation of the planar graph.)

$$s_{ij} := \begin{array}{c} i \quad \bigcirc \quad \bigcirc \quad j \end{array} \quad \text{gives} \quad s_{jk} = (-1)^{2k+2j} \frac{\sin\left(\frac{\pi}{k+2}(2j+1)(2k+1)\right)}{\sin\left(\frac{\pi}{k+2}\right)}$$

**An important identity:**

$$\begin{array}{c} j \\ | \\ i \quad \bigcirc \quad | \\ | \end{array} = \frac{s_{ij}}{s_{0j}} \begin{array}{c} j \\ | \\ | \end{array}$$

## b) Vacuum strands

Vacuum strands are defined as weighted sum over strands labelled by admissible spins:

$$\left| \begin{array}{c} \vdots \\ \vdots \\ \vdots \end{array} \right| := \frac{1}{\mathcal{D}} \sum_k v_k^2 \left| \begin{array}{c} k \\ \vdots \\ \vdots \end{array} \right|$$

$$v_j = (-1)^j \sqrt{d_j}$$

$$\mathcal{D} := \sqrt{\sum_j v_j^4}$$

total quantum  
dimension

A vacuum loop is similar to a  $\delta(g)$  function. Wilson lines (strands) can be deformed across a region enclosed by a vacuum loop.

Sliding property:

$$\left| \begin{array}{c} j \\ \vdots \\ \bullet \end{array} \right| = \left| \begin{array}{c} j \\ \vdots \\ \bullet \end{array} \right|$$

Vacuum loops encircling a strand force the associated spin label to be trivial.

Killing property:

$$\left| \begin{array}{c} j \\ \vdots \\ \bullet \end{array} \right| = \mathcal{D} \delta_{j0}$$

# Hilbert space for (2+1)D: Bases

[Kohno 1992; Alagic et al 2010]

For the torus:

Basis states parametrized by two spins  $(j_u, j_o)$  labelling an under- and over-crossing strand.

We will see that this basis diagonalizes over- and under-crossing Wilsonloops parallel to the vacuum loop.

S-transformation (generalized Fourier transformation):

$$S_{j_o j_u, k_o k_u} = \frac{1}{\mathcal{D}^2} S_{j_o k_o} S_{j_u k_u}$$

# Hilbert space for $(2+1)D$ : Bases

[ Kohn 1992; Alagic et al 2010]

For  $g > 1$  surface:

To each pant decomposition of the surface we can associate a basis.

These bases states include a

- set of vacuum loops
- over-crossing graph (dual to vacuum loops)
- under-crossing graph (dual to vacuum loops).

# From $(2+1)D$ to $(3+1)D$

## We discussed:

- choice of basis for  $(2+1)D$  Hilbert space
- consistent operators: under- and over-crossing Wilson loops.

For these constructions braiding relations play a very important role.  
Using the encoding of a 3D manifold into a Heegaard surface we can export these braiding relations to the  $(3+1)D$  theory.

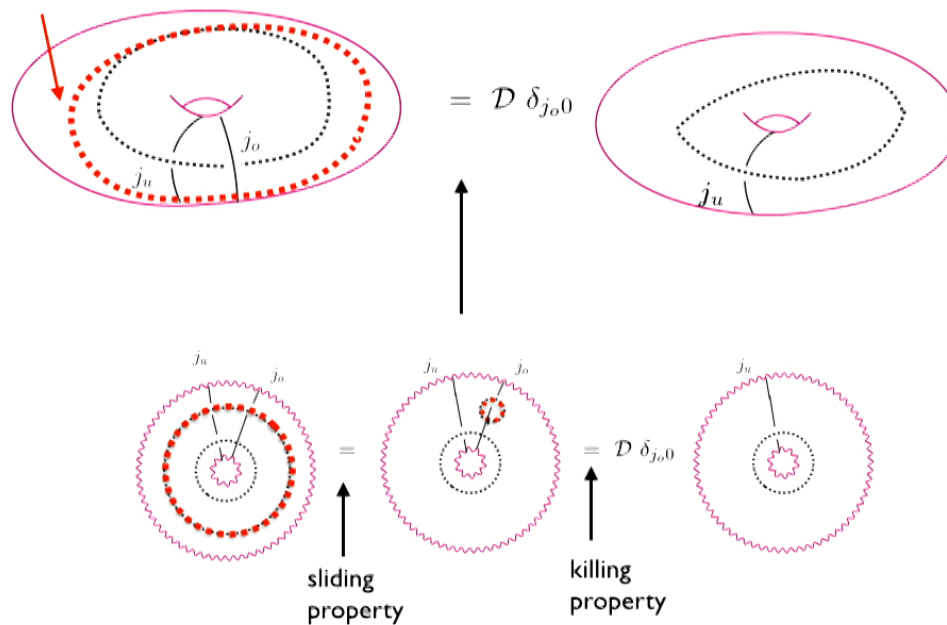

## To proceed:

- a) Construct bases for Heegaard surface.
- b) Impose constraints.
- c) Find operators preserving constraints.

## Example: defect loop in 3-sphere

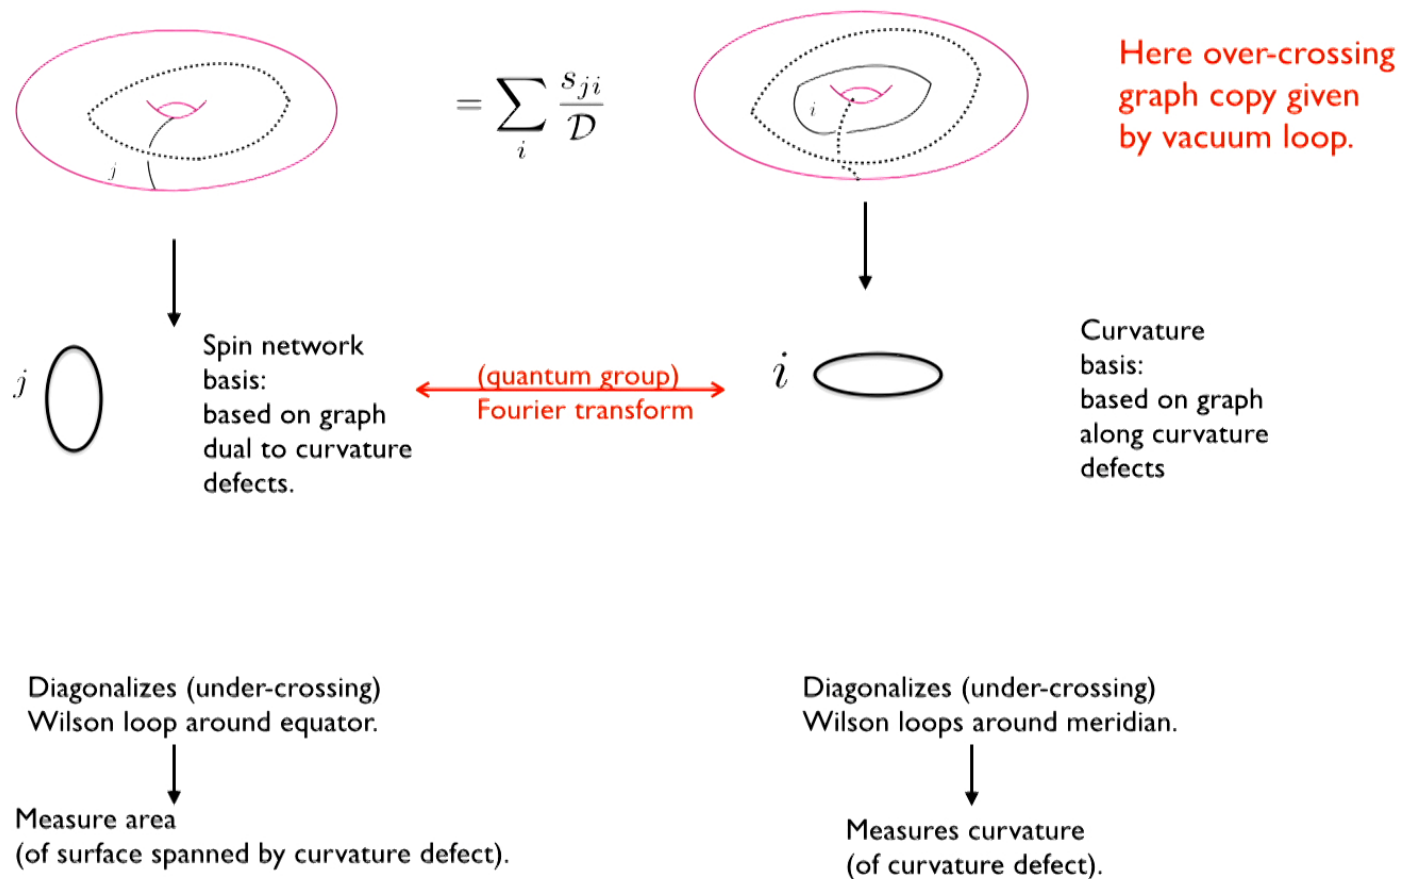

The corresponding Heegaard surface: a torus.  
Flatness constraint along equator of this torus.

flatness constraint (over-crossing vacuum loop)  
along equator

The flatness constraints suppress the over-crossing graph copy.

## Example: defect loop in 3-sphere

# Curvature basis for general 3D triangulation

- Choose pant-decomposition adjusted to the one-skeleton of the triangulation
- After imposing flatness constraints: curvature basis.

Under-crossing graph along one-skeleton of triangulation which can be freely labelled by spins: **labels of the curvature basis**.  
Over-crossing graph given by vacuum loops around triangles.

- (Curvature or Crane-Yetter) vacuum state:  
trivial spins associated to all edges of (triangulation) graph.

Non-degenerate vacuum state for **all topologies**.  
Crane-Yetter invariant is 'trivial'.

Rather hard to see in Walker-Wang formulation.

[ Keyserlingk et al 2013]

# Operators for the (3+1)D theory

Under-crossing Wilson loops preserve flatness constraints.

Wilson loops around triangles.

- diagonalized by spin network basis
- measure area of triangles:

Wilson loops around edges.

- diagonalized by curvature basis
- measures curvature around edges

For normalized  $k$ -Wilson loop:

$$\frac{\sin\left(\frac{\pi}{k+2}(2j+1)(2k+1)\right) \sin\left(\frac{\pi}{k+2}\right)}{\sin\left(\frac{\pi}{k+2}(2k+1)\right) \sin\left(\frac{\pi}{k+2}(2j+1)\right)} \xrightarrow{k \rightarrow \infty} 1 - \frac{8}{3} j(j+1) k(k+1) \left(\frac{\pi}{k+2}\right)^2$$

# Operators for the (3+1)D theory

Under-crossing Wilson loops encode curvature and area operators.

Spectra are discrete and bounded and coincide:

$$\frac{\sin\left(\frac{\pi}{k+2}(2j+1)(2k+1)\right) \sin\left(\frac{\pi}{k+2}\right)}{\sin\left(\frac{\pi}{k+2}(2k+1)\right) \sin\left(\frac{\pi}{k+2}(2j+1)\right)}$$

A self-dual quantum geometry.

# Examples with even more self-duality

quantum-quantum 4-simplex

Curvature basis for 4-simplex.  
(Over-crossing graph copy, which is given by vacuum loops around triangles, is suppressed.)

Spin network basis for 4-simplex.

quantum-quantum 3-torus

Curvature basis for 3 torus with cubical lattice.  
(Over-crossing graph copy and vacuum loops are suppressed.)

Spin network basis for 3-torus.  
(With Vacuum loops suppressed)

Two dual bases for the Walker-Wang model.  
Here operators: under-crossing Wilson-loops on Heegard surface.

# Crane-Yetter simplex amplitude: vacuum state expanded in SNW basis

Curvature basis:  
j=0 for all 15 labels

$$= \sum_j \{15j\}_q$$

Spin network basis:  
all allowed labels

## Conclusions

- general technique to lift Hilbert spaces and operators for a  $(2+1)$ D TQFT to  $(3+1)$ D theory with line defects. We discussed in more detail:
  - Turaev-Viro for modular fusion category: Crane-Yetter with curvature defects
  - BF theory (Turaev Viro for  $\text{Rep}(G)$ ): 4D BF theory with curvature defects
- provides a straightforward analyses of excitations and operator (algebra) of  $(3+1)$ D theories
- e.g.: generalization of fusion basis to  $(3+1)$ D yields an entire family of new bases

# Outlook

- generalizations ala [Baerenz, Barrett 2016]
  - weaken flatness constraints for triangles
  - allows for degenerate ground state (non-trivial 4D invariants)
  - introduces torsion degrees of freedom in addition to curvature defects?
- impose a different excitation content
  - start with Dijkgraaf-Witten models
  - allow for torsion defects instead of curvature defects
- consider boundaries and boundary excitations (in a 'natural' manner: compression bodies) [Keyserlingk et al PRB 2013, ...]
