

Title: Testing Gravity at Extreme Scales

Date: Aug 22, 2017 09:30 AM

URL: <http://pirsa.org/17080023>

Abstract:

Probing gravity at extreme scales

Giorgio Gratta

Physics Dept. Stanford University

What do we know

4

I will briefly discuss a couple of (very different) ideas to extend the measurement reach at the two extremes of the scale.

Perimeter, Aug 2017

G.Gratta, Testing Gravity

5

The long distance regime

There is really nothing like “going there”.

So the plots showing limits on an extra Yukawa terms only tell part of the story.

True modifications of gravity like DGP or MOND are very different and not well described by an extra Yukawa term. And these are models motivated by the Dark Matter and Dark Energy puzzles (even if they may not work well yet)

So “going there” possibly allows to test for the most relevant physics!

B.Buscaino, D.DeBra, P.W. Graham, GG, T.D. Wiser, Phys. Rev. D 92 (2015) 104048

I will briefly discuss a couple of (very different) ideas to extend the measurement reach at the two extremes of the scale.

Perimeter, Aug 2017

G.Gratta, Testing Gravity

5

The long distance regime

Important challenges and requirements:

1) Getting there!

Requires a light payload, heavy launcher, gravitational assists

**2) Drag-free system to minimize interactions with the outside
(except for the gravity from solar system's bodies).**

→ Spacecraft flies around a "Proof Mass" that is truly ballistic

**3) Further identify/fit away interactions of Proof Mass with spacecraft
by rotating the spacecraft perpendicularly to the Sun's direction.**

**4) Good quality telemetry ($R(t)$ and $v(t)$). Because of distance and
spacecraft rotation, require a relay craft, trailing the science
instrument by ~10km.**

5) Reliable (10yr lifetime) drag-free system micro-thrusters.

Instrument/flight parameters

Parameter	Value
Drag Free spacecraft mass	200 kg
Experiment duration	7 yr
Distance reached	100 AU
Proof mass	1 kg
Proof mass radius (Pt)	5 cm
Thruster bandwidth	10^{-2} Hz
Proof mass sensing deadband	10 μ m
Correction period	100 s
Ranging measurement period	20 day
Proof mass discharging period	2 day
Micro-thrusters fuel mass (FEEPs)	<50g
Spacecraft angular velocity	0.1 Hz
Spacecraft radial initial velocity	14 AU/yr
Relay craft distance	~10 km
RTG power	<1 kW

Red is technically challenging

Assume that a mission to 100AU with a ~2yr maneuvering phase and a ~5yr coast is feasible

[from R.A. Mewaldt et al., Acta Astron. 35 (1995) 267]
Realistic navigation with realistic launch windows needs to be designed by experts

Assume ~100 AU max distance

Maneuvering propulsion stage jettisoned before coast (when relay craft undocks and proof mass is released).

Dominant systematics

- Non-solar gravity in the solar system
 - Mass and density distribution of Kuiper Belt very poorly known
 - Best trajectory is polar; this can be achieved with one last gravitational assist designed to deflect the craft \perp to the ecliptic plane (unique viewpoint of the Solar System!)
 - As a by-product the mission would measure
$$\delta GM_{KB} \sim 5 \times 10^{-4} GM_{Earth} = 0.5\% @ GM_{KB}^{MAX} = 0.1 GM_{Earth}$$
and KB's mass weighed radius and ecliptic plane offset
- Ranging accuracy
 - Assume 1 m accuracy (this is conservative; feasible now with NASA DSN and "off the shelf" transponders)
 - Also use an aggressive option with 10 cm accuracy (possible with laser ranging under development)

Effect of the Kuiper Belt with a 1 m ranging accuracy, polar trajectory

Projected accuracy for Yukawa parameters

... and for non-Yukawa modification of gravity going to 100 AU is key.

If we are lucky we'll start a better study in the fall with JPL

Possible improvements:

- *Maybe they can go to 500AU in a reasonable time
(this involves scary, very short distance flybys...)*
- *Maybe the 10cm ranging accuracy is conservative
and 1cm is aggressive.*
- *Some engineering by someone who knows this stuff!*

Short distance regime: the challenges

1. **G is very small (gravity is very weak). Since gravity can't be shielded this is not obvious in very large objects.**
2. Since $F = G \frac{M_1 M_2}{R^2} = G \frac{\rho_1 V_1 \rho_2 V_2}{R^2}$
for materials we have access to (no Neutron Stars here!)
 $\rho_1 \sim \rho_2 < 20 \text{ g/cm}^3$, there is no silver bullet.
In addition $V \sim R^3$, so $F \sim G \frac{\rho^2 R^6}{R^2}$ It is clear that
measurements at short distance become exceedingly difficult.
Often the measured quantity is the acceleration of the test
mass: $a \sim G \frac{\rho R^3}{R^2} \sim G \rho R$
3. At distances $< 100 \mu\text{m}$ even neutral matter results in residual
E&M interaction that are a dangerous background for
these measurements

Sketch of the EotWash apparatus from the University of Washington in Seattle

Most inverse-square law measurements done with wonderfully sophisticated versions of Cavendish's setup.

As distances become shorter substantial efforts have to do with “artificial” issues (e.g. how to machine a 5 cm diameter disk flat to μm level...).

In addition most previous measurements use mechanical springs.

We use a force sensor similar in size to the range of interest and use “optical springs” that are much more versatile than the mechanical ones.

[Note: The ideal probe for such a measurement would be a neutron, because its charge radius is $\sim 1\text{fm}$ instead of $\sim 1\text{nm}$ (for atoms). Unfortunately we do not know how to manipulate a neutron sufficiently well to use it for these measurements.]

Optical traps offer important advantages

- In high vacuum can cool the force sensor (μ sphere) with everything else at room temperature.
- Thermal and vibrational noise from mechanical support minimized.
- Test mass position can be controlled and measured precisely with optics.
- Trap parameters can be changed instantaneously.
- Control of optical potential and motion in all 3 DOF allows powerful differential measurements.
- Dielectric spheres from ~ 10 nm to $10\ \mu\text{m}$ commercially available.
- Extremely low dissipation is possible:
 $Q \sim 10^{12}$ at 10^{-10} mbar

Ashkin & Dziedzic, *Appl. Phys. Lett.* 19 (1971) 283
Geraci et al., *PRL* 105 (2010) 101101
Ranjit et al., *Phys. Rev. A* 91 (2015) 051805(R)

Trap loading

- Microspheres are launched from bottom surface of quartz cantilever
- Pull-off forces of ~ 100 nN require accelerations $\sim 10^6$ m/s²
- Bottom coverslip protects lens and is retracted after trapping

Schematic of microsphere dropper:

Perimeter, Aug 2017

Pull-off force vs. microsphere radius:

Microspheres on quartz surface:

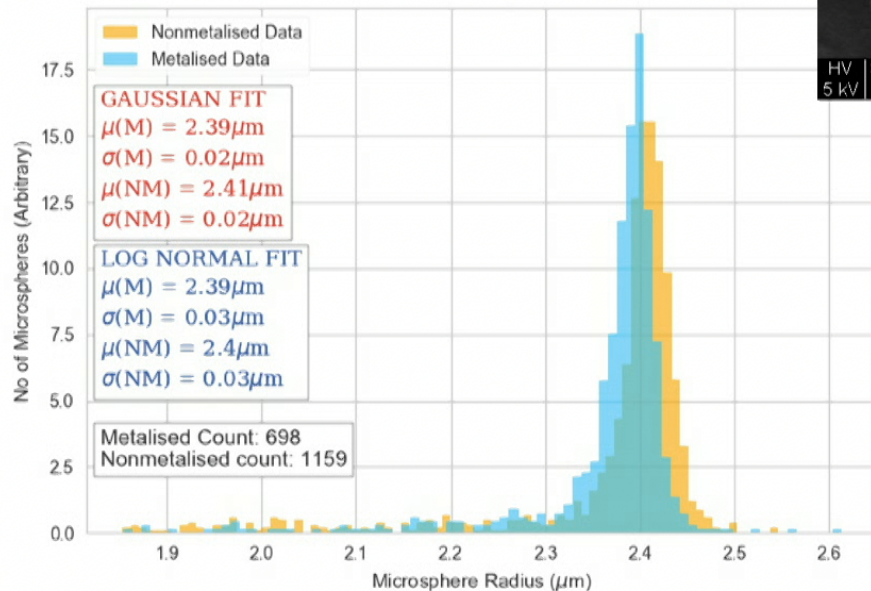

G.Gratta, Testing Gravity

17

**Our SEM analysis of 5µm diameter
solution-grown silica microspheres**

$$\sigma(R)/R \sim 1\%$$

$$e = \sqrt{1 - \left(\frac{R-\epsilon}{R+\epsilon}\right)^2} \rightarrow \sigma(e) \sim 5\%$$

Perimeter, Aug 2017

G.Gratta, Testing Gravity

**Microspheres also exist made of
fused silica, titania, zirconia,
sapphire and various plastics.**

**They can also have functional
groups (COOH, NH₂) attached to
their surface.**

18

Initial, simplified optics setup

- 1064 nm trapping laser, up going using single mode fiber as spatial mode cleaner
- 650 nm imaging laser
- Position sensitive PD for high bandwidth feedback and CCD cameras for imaging
- FPGA forms feedback signals on the laser power (vertical) and beam steering (horizontal) DOFs
- μ spheres are dropped in ~ 1 mbar N_2 from a vibrating quartz beam
- System pumped to $\sim 10^{-6}$ mbar while starting the feedback cooling

Can readily cool μ spheres to <100 mK, with everything else in the apparatus being at room temperature.

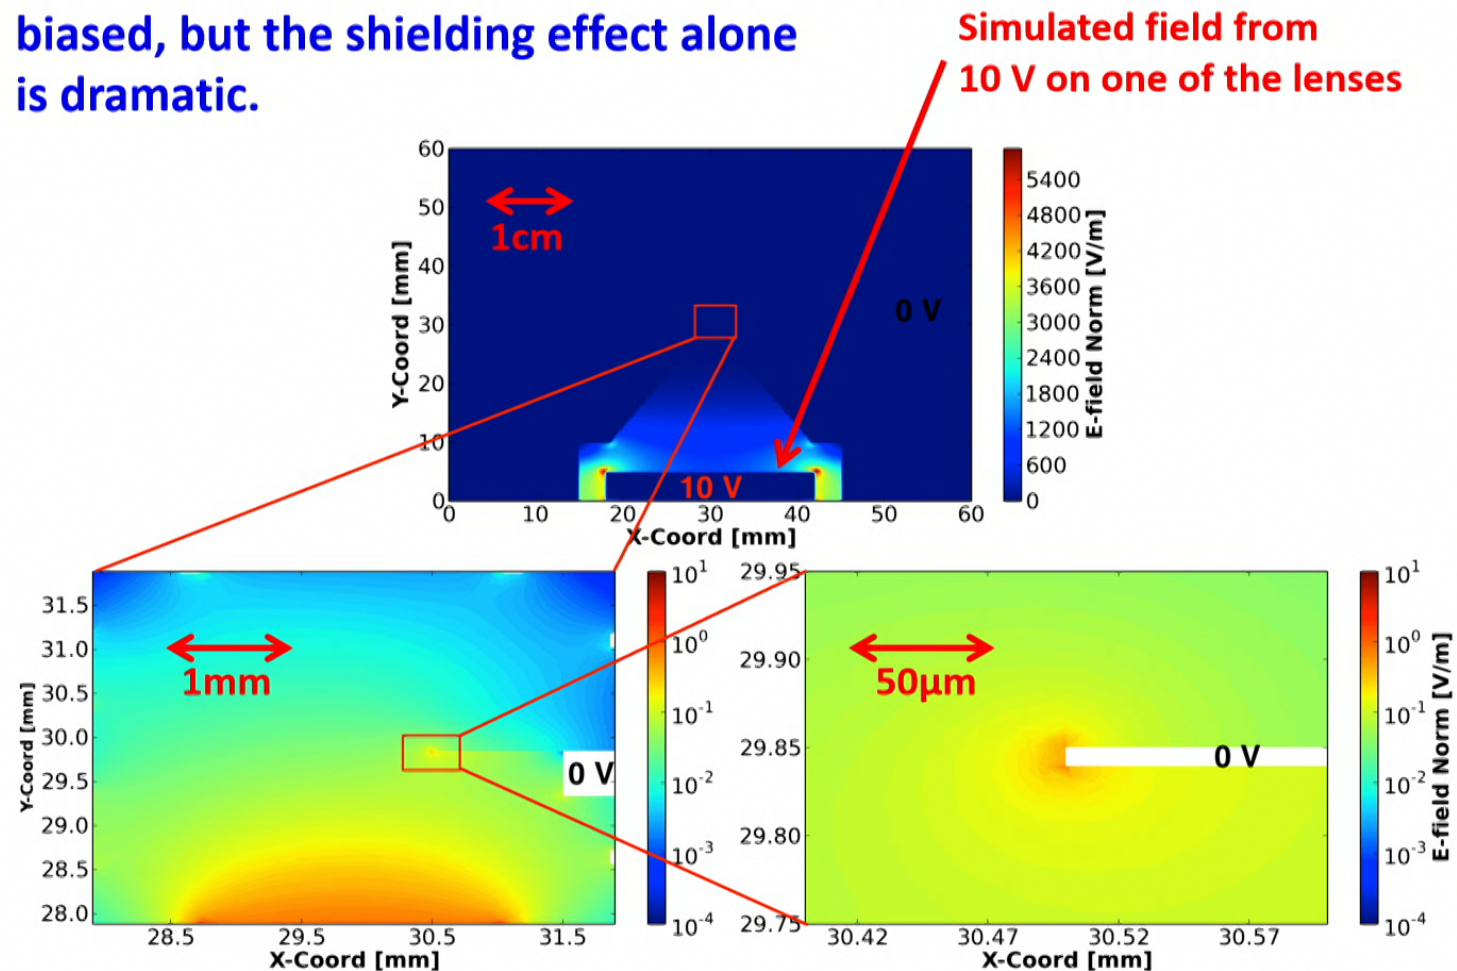

- *Note that this is the “temperature” of the center-of-mass DOFs. We do not know the internal temperature of the μ sphere.*
- *Can maintain μ spheres in this state for days.*

Important to provide good charge control around microsphere (even for microspheres that are overall neutral)

- ➔ Shield possible static charges on the trapping and imaging lenses
- ➔ Allow for the option of tweaking the potentials of each of the 6 sides of the

Each of the 6 funnels can be independently biased, but the shielding effect alone is dramatic.

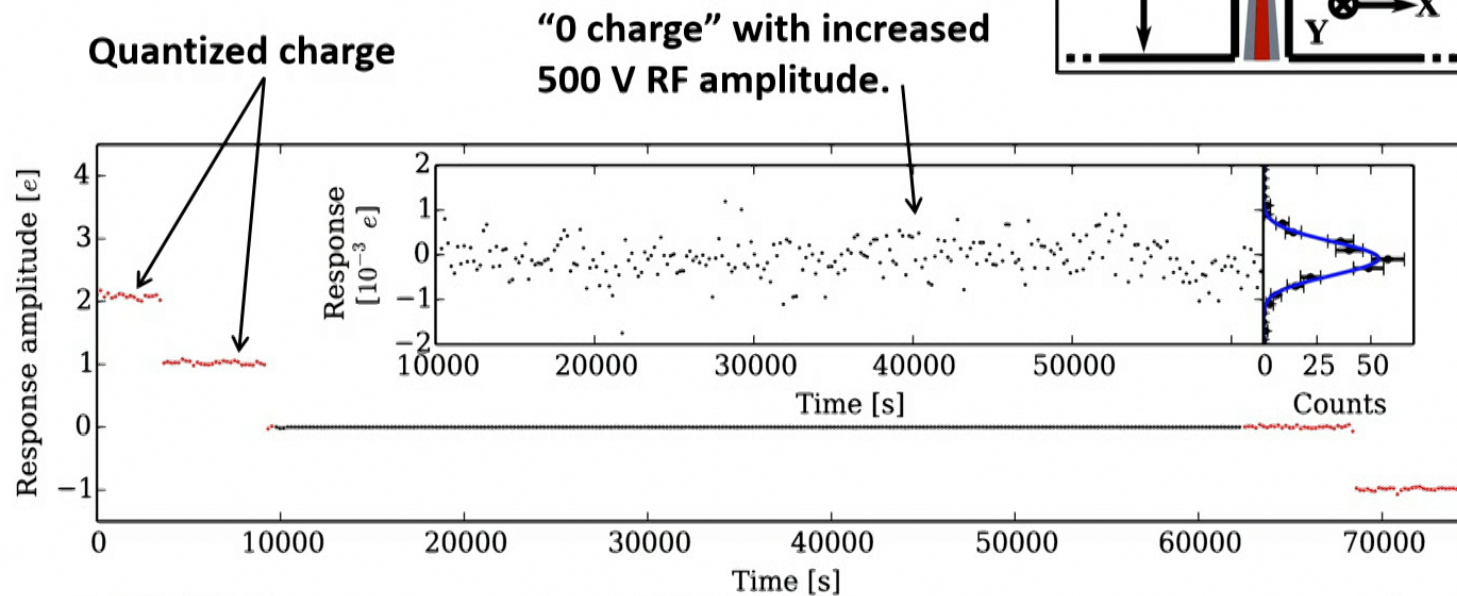

Perimeter, Aug 2017

G.Gratta, Testing Gravity

22

μ spheres are often left in a charged state after being trapped.

- This can be measured by applying an RF potential to a set of plates
- μ spheres are discharged by flashing a UV light.
- Probably this means that one can't use UV for the trapping laser

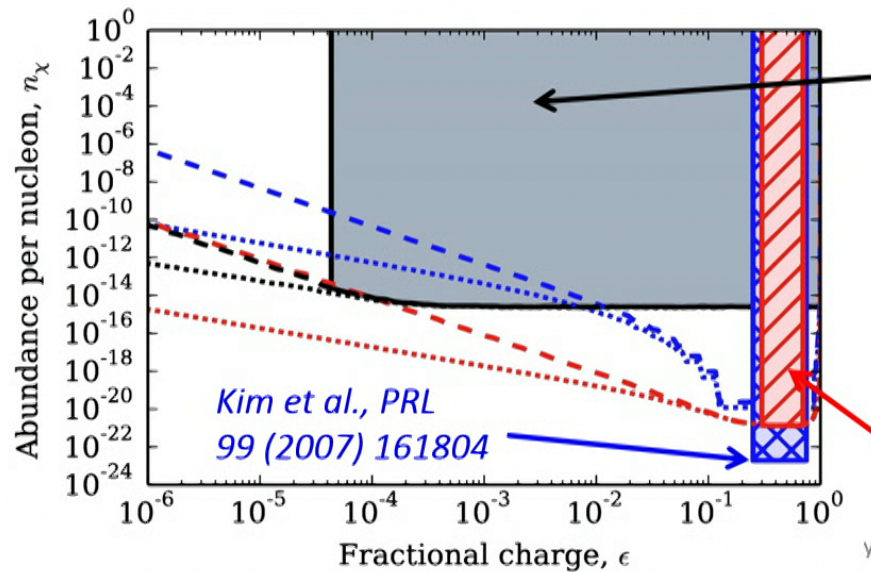

Perimeter, Aug 2017

G.Gratta, Testing Gravity

23

**How close to 0
is “0 charge”?**

**There are small residuals
but the response is not
consistent with an
effective charge.**

The largest residual can be conservatively used as a limit to particles with a “millicharge” bound into/onto the μ spheres.

Screened scalars: a “low-hanging fruit” along the way to gravity

Theories of Dark Energy introduce scalar fields that can get around the present limits on long range forces and go undetected because of screening in regions of high mass density
(basically, the field has finite values only in vacuum)
→ Hence the name Chameleon for some of the scalars!

34

Electrostatic background

Neutral microspheres contain $\sim 10^{14}$ electric charges and interact primarily as dipoles:

$$\vec{F} = (\vec{p} \cdot \vec{\nabla}) \vec{E} \Rightarrow F_z \approx \underbrace{(p_{0z})}_{\text{Permanent dipole}} + \underbrace{\alpha E_z}_{\text{Induced dipole}} \frac{\partial E_z}{\partial z}$$

FEM calculation of electric potential:

Perimeter, Aug 2017

Force for permanent and induced dipole:

G.Gratta, Testing Gravity

35

This background is measured:

- Bias cantilever to from 1 to 5 V and sweep its position
- Fits to distance dependence allow determination of permanent and induced dipole moments

Microsphere response vs. distance:

Perimeter, Aug 2017

G.Gratta, Testing Gravity

Fits to dipole response:

Microsphere	p_{0z} [$e \mu\text{m}$]	α/α_0
#1	151 ± 6	0.21 ± 0.13
#2	89 ± 10	0.00 ± 0.33
#3	192 ± 30	0.25 ± 0.14

Polarizability, α , measured relative to:

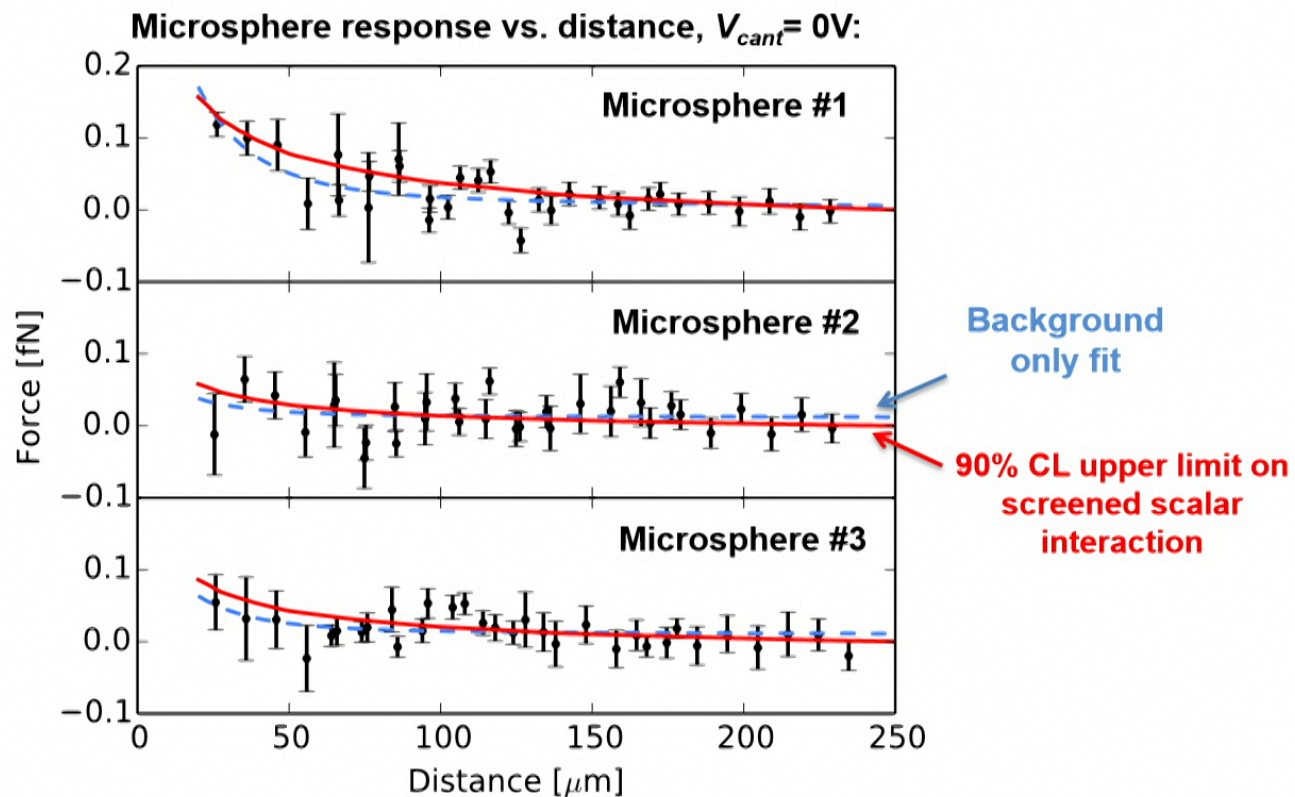

$$\alpha_0 = 3\epsilon_0 \left(\frac{\epsilon_r - 1}{\epsilon_r + 2} \right) \left(\frac{4}{3} \pi r^3 \right)$$

for $\epsilon_r \approx 3$, $r = 2.5 \mu\text{m}$ (but our microspheres may not behave like bulk silica)

36

Then perform measurement with cantilever at “nominal 0 V”

Residual response consistent with <30 mV contact potentials

Perimeter, Aug 2017

G.Gratta, Testing Gravity

37

Results *(A.Rider et al. Phys. Rev. Lett. 117 (2016) 101101)*

- Consistent with background-only model at 90% CL
- Sensitivity limited by electrostatic backgrounds, and unable to constrain models with $\Lambda = 2.4$ meV due to self-screening
- Constraints can be set at $\Lambda > 4.6$ meV where self-screening is reduced

Substantially better sensitivity should be achievable with better electrostatic control

Perimeter, Aug 2017

G.Gratta, Testing Gravity

38

A better optical setup with heterodyne/interferometric readout

- Suppress background scattered from near-by attractor (scattered light has wrong phase relationship)
- Absolutely calibrated vertical position (vertical DOF readout interferometrically from back-reflected light)
- True single-beam and single-frequency operation

Onwards to gravity...

Structured attractor can mitigate many backgrounds present for uniform cantilever (only move perpendicularly to the force direction)

Schematic of density structured probe mass:

Perimeter, Aug 2017

G.Gratta, Testing Gravity

40

This is mounted on a fast flexure stage
to swing it in front of the μ sphere.

Perimeter, Aug 2017

41

Si-Au attractors fabricated and ready for use

Perimeter, Aug 2017

G.Gratta, Testing Gravity

42

Better laser mode to limit light scattered from near-by attractor

Radius of circular region at z_{trap} (μm)	Power in (new) beam halo (%)
2.5	0.7-0.8
5	0.5-0.6
10	0.2

Concept of attractor with stationary shield

Fabrication technology
very similar to the
one already defined

Drive mechanism
not yet designed

Stationary shield can
also be retrofitted
on other, existing
designs

Concepts for fluidic periodic attractors

Example of microchannel in Si
deBoer et al J Microelectromechanical Sys 9 (2000) 94

Expected backgrounds: Casimir forces

Coating the attractor with $t = 0.5 - 3 \mu\text{m}$ thick Au should sufficiently suppress the differential Casimir force

Topography and surface potential for sputtered Au film:

- Have estimated background using patch measurements of Au films
- Possibly amorphous graphite coatings have smaller patch potentials.

Expected backgrounds: Patch potentials

- Deposited Au films typically have potential variations $\sim 10\text{--}100$ mV over 10-1000 nm surface regions
- Such “patch potentials” have been studied extensively in previous work

Projected sensitivity

- Parametrization:
$$V(r) = -\frac{Gm_1m_2}{r} \left(1 + \alpha e^{-r/\lambda}\right)$$

- Assumptions:

Force sensitivity:

$\sigma_F = 2 \times 10^{-17} \text{ N Hz}^{-1/2}$
(already achieved)

σ_F = pressure limited at
 10^{-9} mbar (red)

10^5 s integration time

Attractor distance $s = 2 \mu\text{m}$

Backgrounds:

At or below noise level,

Au shield thick enough to
suppress Casimir background

- Substantial improvement over existing limits should be possible between 1 and 40 μm

Existing limits are the envelope of:

Chen et al, PRL 116 (2016) 221102 (micromechanical torsion oscillator)

Sushkov et al, PRL 107 (2011) 171101 (torsion pendulum)

Geraci et al, PRD 78 (2008) 022002 (microcantilever)

Kapner et al, PRL 98 (2007) 021101 (torsion pendulum)

Summary

- Dark Matter and Dark Energy, along with theoretical difficulties in quantum gravity suggest that gravity is the next frontier!
- The experimental study of gravity at extreme scales may reveal exciting physics beyond the SM.
- Developed a technique to measure very small forces at $<50\mu\text{m}$ distance using dielectric $\mu\text{spheres}$ and optical tweezers.
- The power of the technique was demonstrated by searches for millicharge particles and screened scalars.
- Force measurements with this technique at the quantum limit may substantially advance our understanding of fundamental physics (see also Andy's talk!)
- There are more applications to fundamental measurements, some known, some unknown! Help us figure out what else to use this for!
