Date: April 25, 2019 - 10:45 AM

URL: <http://pirsa.org/19040113>

Abstract: We introduce an isometric restriction of the tensor-network ansatz that allows for highly efficient contraction of the network. We consider two concrete applications using this ansatz. First, we show that a matrix-product state representation of a 2D quantum state can be iteratively transformed into an isometric 2D tensor network. Second, we introduce a 2D version of the time-evolving block decimation algorithm (TEBD2) for approximating the ground state of a Hamiltonian as an isometric tensor network, which we demonstrate for the 2D transverse field Ising model.

DMRG finds ground states of Hamiltonians in a time polynomial in system size: for gapped states, effectively linear in L

Unbiased: variants of DMRG provably work for any gapped phase

Easy to get e.g. 12 digit accuracy in observables

Generalizations to time dependence, finite T , etc.

Generalizing it's success to 2D would be great!

The underlying engine: 1D tensor network ansatz (matrix product state)

[Fannes et al. 1992;
Östlund & Rommer 1995]

MPS: variational ansatz for spin-chains

$$|\Psi\rangle = \sum_{\alpha, n} [\cdots B_{\alpha_1 \alpha_2}^{n_1} B_{\alpha_2 \alpha_3}^{n_2} \cdots] |\cdots n_1 n_2 \cdots\rangle \quad n_i = \uparrow / \downarrow$$

$$\Psi \cdots n_0 n_1 \cdots = \cdots \begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\ \quad n_{-1} \quad n_0 \quad n_1 \quad n_2 \\ \quad \quad \quad \downarrow \\ \quad \quad \quad B \end{array} \cdots$$

$$B_{\alpha\beta}^n = \alpha \begin{array}{c} \text{---} \text{---} \\ \quad \downarrow \\ \quad n \end{array} \beta \quad \alpha, \beta \in \{1, 2, \dots, D\}$$

$D =$ bond dimension / tensor size

The underlying engine: 1D tensor network ansatz (matrix product state)

[Fannes et al. 1992;
Östlund & Rommer 1995]

MPS: variational ansatz for spin-chains

$$|\Psi\rangle = \sum_{\alpha, n} [\cdots B_{\alpha_1 \alpha_2}^{n_1} B_{\alpha_2 \alpha_3}^{n_2} \cdots] |\cdots n_1 n_2 \cdots\rangle \quad n_i = \uparrow / \downarrow$$

$$\Psi \cdots n_0 n_1 \cdots = \cdots \begin{array}{c} \text{---} B \text{---} \\ | \quad | \quad | \quad | \\ n_{-1} \quad n_0 \quad n_1 \quad n_2 \\ \text{---} \end{array} \cdots$$

$$B_{\alpha\beta}^n = \begin{array}{c} \alpha \text{---} \beta \\ | \\ n \end{array} \quad \alpha, \beta \in \{1, 2, \dots, D\}$$

$D = \text{bond dimension / tensor size}$

DMRG is method to variationally minimize energy by sequentially tweaking the "B":

$$E_0 = \min_{\{B\}} \frac{\langle \Psi | H | \Psi \rangle}{\langle \Psi | \Psi \rangle}$$

2D: TNSs ... will eventually work really really well?

(alias "projected entangled pair / PEP")

Theoretical: what phases can be well approximated by PEPs?
How does error scale with bond dimension "D"?

Practical: how do we efficiently compute observables and
optimize tensors?

[Susanne Richter 1996 (!); Nishino, Okunishi et al. 2001; Verstraete & Cirac 2004;]

Practical: how do we efficiently compute observables and optimize tensors?

Typical object to compute: $E = \min_{\{T\}} \frac{\langle \Psi | H | \Psi \rangle}{\langle \Psi | \Psi \rangle}$

Let's start easy, with the norm:

$$\langle \Psi | \Psi \rangle = \text{[Diagram of a 3D grid of vertical and horizontal lines representing a tensor network]} = \sum_{\{\alpha, \bar{\alpha}\}=1}^D T^* T_{\bar{\alpha}_1 \alpha_1} T^* T_{\bar{\alpha}_2 \alpha_2} \dots$$

$D^{4L_x L_y}$ terms, obviously
can't be contracted exactly

Need approximation algorithm: *like* computing partition function of 2D classical model

Boundary MPS method

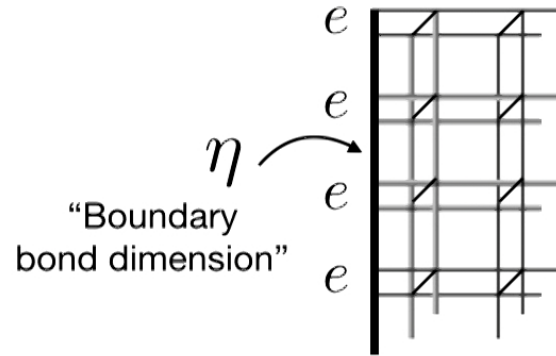

[Verstraete & Cirac 2004; many since;
CTMRG Nishino, Okunishi et al. 2001]

$$E_L^{[2]}$$

Approximate
boundary
as MPS:

$$E_L^{[2]} \approx eee \dots$$

"Column transfer operator"

$$E_L^{[3]} = T^\dagger E_L^{[2]} T =$$

MPS
compression
 \approx

Boundary MPS method

Leading costs:
(VUMPS-based) $\mathcal{O}(\eta^3 D^4 + \eta^2 D^6)$
[Fishman, et. al. 2018]

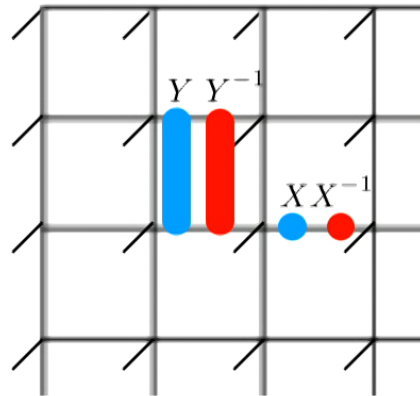

Empirically it is found $\eta \gg D$ e.g., for 2D Heisenberg model $D = 5, \eta = 100$

Calculating environments is dominant cost of PEPS

- 1) **The isometric TNS variational ansatz**
- 2) Variational power of isoTNS
- 3) Algorithms: Moses Move, TEBD^2 , DMRG^2

Gauge redundancy

The TNS is a many-to-one mapping:
we can insert XX^{-1} into any bond
and absorb into neighboring tensors

Single-leg transformations don't change bond dimension "D"
But current boundary MPS methods, e.g. VUMPS, *not* invariant under them: will change η

Multi-leg transformations change D; generically increase D,
but up to small error could also *decrease* D

It is natural to try and fix this redundancy by demanding tensors
satisfy some additional conditions, i.e. a "canonical form"

The key property we will try to enforce:

$$E_L^{[2]} = \mathbb{1}$$

$$\sum_{a, a'} \delta_{aa'}$$

∧

∧

∧

We require environments from E, N, S, W be trivial

This is special property of tensors which *cannot* be achieved by one-leg gauge redundancy; *will change D*

The key property we will try to enforce:

$$E_L^{[2]} = \mathbb{1}$$

This is special property of tensors which *cannot* be achieved by one-leg gauge redundancy; *will change D*

Down with environments!

Review of 1D canonical form

We assign arrows to a matrix if it is *isometry*:
a unitary with some columns dropped

$$\begin{array}{c}
 \text{UV} \xrightarrow{\quad A \quad} \text{IR} \\
 A^\dagger A = \mathbb{1}_{IR} \\
 AA^\dagger = P_{UV}, P_{UV}^2 = P_{UV}
 \end{array}
 \quad
 \begin{array}{c}
 \begin{array}{c}
 \xrightarrow{A} \\
 \bullet \\
 \xrightarrow{A^*}
 \end{array}
 = \left(\begin{array}{c} \mathbb{1} \\ \\ \end{array} \right)
 \end{array}$$

Review of 1D canonical form

We assign arrows to a matrix if it is *isometry*:
a unitary with some columns dropped

$$UV \xrightarrow{A} IR \quad \begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \text{---} \xrightarrow{A^*} \text{---} \end{array} = \mathbb{1}$$

$$A^\dagger A = \mathbb{1}_{IR}$$

$$AA^\dagger = P_{UV}, P_{UV}^2 = P_{UV}$$

Extends to tensors by grouping in / out legs:

$$\begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \uparrow \end{array} \rightarrow \begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \text{---} \xrightarrow{A^*} \text{---} \\ \uparrow \end{array} = \mathbb{1}$$

$$\begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \searrow \end{array} \rightarrow \begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \text{---} \xrightarrow{A^*} \text{---} \\ \searrow \end{array} = \begin{array}{c} \mathbb{1} \\ \mathbb{1} \\ \mathbb{1} \\ \mathbb{1} \end{array}$$

Review of 1D canonical form

We assign arrows to a matrix if it is *isometry*:
a unitary with some columns dropped

$$UV \xrightarrow{A} IR \quad \begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \text{---} \xrightarrow{A^*} \text{---} \end{array} = \mathbb{1}$$

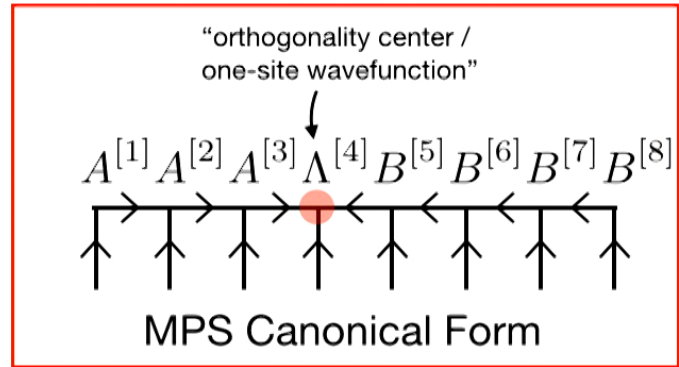

$$A^\dagger A = \mathbb{1}_{IR}$$

$$AA^\dagger = P_{UV}, P_{UV}^2 = P_{UV}$$

Extends to tensors by grouping in / out legs:

$$\begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \uparrow \\ \text{---} \end{array} \rightarrow \begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \uparrow \\ \text{---} \xrightarrow{A^*} \text{---} \end{array} = \mathbb{1}$$

$$\begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \uparrow \downarrow \\ \text{---} \end{array} \rightarrow \begin{array}{c} \text{---} \xrightarrow{A} \text{---} \\ \uparrow \downarrow \\ \text{---} \xrightarrow{A^*} \text{---} \\ \uparrow \downarrow \\ \text{---} \end{array} = \begin{pmatrix} \mathbb{1} & & & \\ & \mathbb{1} & & \\ & & \mathbb{1} & \\ & & & \mathbb{1} \end{pmatrix}$$

Any MPS can be brought to canonical form *without increasing D*

1D Canonical form = trivial environments

$$\begin{aligned}
 \langle \Psi | \Psi \rangle &= \begin{array}{c} A^{[1]} A^{[2]} A^{[3]} \Lambda^{[4]} B^{[5]} B^{[6]} B^{[7]} B^{[8]} \\ \text{Diagram with 8 sites, arrows pointing right then left, and red dots at site 4} \end{array} \\
 &= \text{iso.} \left(\begin{array}{c} \text{Diagram with 6 sites, arrows pointing right then left, and red dots at site 4} \end{array} \right) \\
 &= \text{iso.} \left(\begin{array}{c} \text{Diagram with 4 sites, arrows pointing right then left, and red dots at site 4} \end{array} \right) \\
 &\quad \dots \\
 &= \begin{array}{c} \Lambda^{[4]} \\ \text{Diagram with 2 sites, arrows pointing right then left, and red dots at site 4} \end{array} = \langle \Lambda | \Lambda \rangle = 1
 \end{aligned}$$

Local observables determined by 1-site wavefunction Λ

$$\begin{aligned}
 \langle \Psi | \mathcal{O} | \Psi \rangle &= \begin{array}{c} A^{[1]} \ A^{[2]} \ A^{[3]} \ \Lambda^{[4]} \ B^{[5]} \ B^{[6]} \ B^{[7]} \ B^{[8]} \\ \text{Diagram of a chain with 8 sites, with arrows and a central operator } \mathcal{O} \end{array} \\
 &= \text{iso.} \left(\begin{array}{c} \text{Diagram of a chain with 8 sites, with arrows and a central operator } \mathcal{O} \end{array} \right) \\
 &= \text{iso.} \left(\begin{array}{c} \text{Diagram of a chain with 4 sites, with arrows and a central operator } \mathcal{O} \end{array} \right) \\
 &\quad \dots \\
 &= \left(\begin{array}{c} \Lambda^{[4]} \\ \text{Diagram of a chain with 4 sites, with arrows and a central operator } \mathcal{O} \end{array} \right) = \langle \Lambda | \mathcal{O} | \Lambda \rangle
 \end{aligned}$$

2D generalization: "isometric TNS"

Norm of isoTNS

Reduces to norm of 1D Λ , which reduces to norm of 0D λ

Environments of isoTNS

$$E_L^{[1]}$$

$$E_L^{[1]} = \mathbb{1}$$

And so on by induction - $E_L^{[2]} = \mathbb{1}, \dots$
until you hit orthogonality center

Environments of isoTNS

$$E_L^{[1]}$$

$$E_L^{[1]} = \mathbb{1}$$

And so on by induction - $E_L^{[2]} = \mathbb{1}, \dots$
until you hit orthogonality center

In fact, any boundary which is
“space-like,” with only *outgoing*
arrows, will have a trivial environment

Orthogonality center

Λ really is the wave-function: the tensors in the surrounding quadrants are an *orthonormal* change of basis (isometry) from physical to ancilla space

Λ is sufficient to calculate the entanglement spectrum of any combo of quadrants

Efficient two-point functions

Dimensional reduction to 1D MPS VEV = Efficiently computable $\mathcal{O}(\eta^3 D^2)$

Efficient two-point functions

Dimensional reduction to 1D MPS VEV = Efficiently computable $\mathcal{O}(\eta^3 D^2)$

Corollary: *iso-TNS have exponentially decaying correlations*
 In contrast, generic TNS can have algebraic correlations (Ising PEPs)
 [But: algebraic \neq 2D CFTs. See A. Läuchli's talk]

Efficient two-point functions

OK, but what if points aren't on Λ ?

O_i will spoil isometry condition in future light cone:
 they will grow under *dissipative* Heisenberg evolution
 (quantum channel)

Efficient two-point functions

OK, but what if points aren't on Λ ?

We need a way to move Λ around...
I'll return to this! ("MOSES MOVE")

O_i will spoil isometry condition in future light cone:
they will grow under *dissipative* Heisenberg evolution
(quantum channel)

Variational power?

iso-TNS \subset all PEPs

Is it a useful subset?

What phases have iso-TNS representation?

What entanglement properties determine convergence behavior?

Variational power: at least SRE and non-chiral topo. order

1) All string net states can be exactly put in iso-TNS form

Folklore: any gapped 2D phase with “gappable” edges (e.g., non-chiral) has string net representative

[Levin & Wen, PRB 2004]

2) If $|\Phi\rangle$ is iso-TNS, and U is finite-depth circuit, then $U|\Phi\rangle$ has exact iso-TNS form

Variational power: at least SRE and non-chiral topo. order

1) All string net states can be exactly put in iso-TNS form

Folklore: any gapped 2D phase with “gappable” edges (e.g., non-chiral) has string net representative

[Levin & Wen, PRB 2004]

2) If $|\Phi\rangle$ is iso-TNS, and U is finite-depth circuit, then $U|\Phi\rangle$ has exact iso-TNS form

1+2): roughly speaking - all 2D gapped *phases* with gappable edges have iso-TNS form

(However - does not estimate error to *approximate* state with given bond dimension)

All string net states can be exactly put in iso-TNS form

Tensor network representation of string nets known

Data from TQFT \longrightarrow String-net construction \longrightarrow TNS representation

$$\begin{aligned} \Phi \left(\begin{array}{c} \square \quad \square \\ | \\ \square \end{array} \right) &= \Phi \left(\begin{array}{c} \square \quad \square \\ \text{---} \\ \square \end{array} \right) \\ \Phi \left(\begin{array}{c} \square \\ \square \quad \square \end{array} \right) &= d_i \Phi \left(\begin{array}{c} \square \\ \square \end{array} \right) \\ \Phi \left(\begin{array}{c} \square \quad \square \\ \uparrow \quad \downarrow \\ \square \quad \square \end{array} \right) &= \delta_{ij} \Phi \left(\begin{array}{c} \square \quad \square \\ \uparrow \quad \downarrow \\ \square \quad \square \end{array} \right) \\ \Phi \left(\begin{array}{c} \square \quad \square \\ \uparrow \quad \downarrow \\ \square \quad \square \end{array} \right) &= \sum_n F_{klm}^{ijn} \Phi \left(\begin{array}{c} \square \quad \square \\ \uparrow \quad \downarrow \\ \square \quad \square \end{array} \right) \end{aligned}$$

[Levin & Wen, PRB 2004]

$$= \delta_{\alpha\alpha'} \delta_{\beta\beta'} \delta_{\gamma\gamma'} \frac{d_a^{\frac{1}{2}} d_b^{\frac{1}{2}} F_{ac\beta}^{ab\gamma}}{d_c^{\frac{1}{2}} \sqrt{d_\beta}}$$

Entries of tensors given by TQFT data

[Buerschaper et al. 2008; Gu et al. 2008; Williamson et al. 2017]

All string net states can be exactly put in iso-TNS form

Tensors can be massaged with gauge transformations:

All string net states can be exactly put in iso-TNS form

Tensors can be massaged with gauge transformations:

Choosing X, Y, Z related to d_a and using the unitarity properties of F-matrices

$$\left[F_d^{abc} \right] \left[F_d^{abc} \right]^\dagger = \mathbb{1} = \left[F_{cd}^{ab} \right] \left[F_{cd}^{ab} \right]^\dagger$$

+ some other TQFT relations, can be made isometric tensor-by-tensor

All string net states can be exactly put in iso-TNS form

Tensors can be massaged with gauge transformations:

Choosing X, Y, Z related to d_a and using the unitarity properties of F-matrices

$$\left[F_d^{abc} \right] \left[F_d^{abc} \right]^\dagger = \mathbb{1} = \left[F_{cd}^{ab} \right] \left[F_{cd}^{ab} \right]^\dagger$$

+ some other TQFT relations, can be made isometric tensor-by-tensor

$$\Lambda = \begin{array}{c} a \\ | \\ \cdots \\ | \\ a' \end{array} \cdots \begin{array}{c} b \\ | \\ \cdots \\ | \\ b' \end{array} \cdots = \cdots d_a \delta_{aa'} d_b \delta_{bb'} \cdots$$

Orthogonality center is tensor-product of quantum dimensions; produces correct entanglement spectrum etc.

If $|\Phi\rangle$ is iso-TNS, and U is finite-depth circuit, then $U|\Phi\rangle$ has exact iso-TNS form

- 1) Course-graining move
- 2) Onsite-unitary move (preserves iso-TNS)
- 3) Fine-graining move

If $|\Phi\rangle$ is iso-TNS, and U is finite-depth circuit, then $U|\Phi\rangle$ has exact iso-TNS form

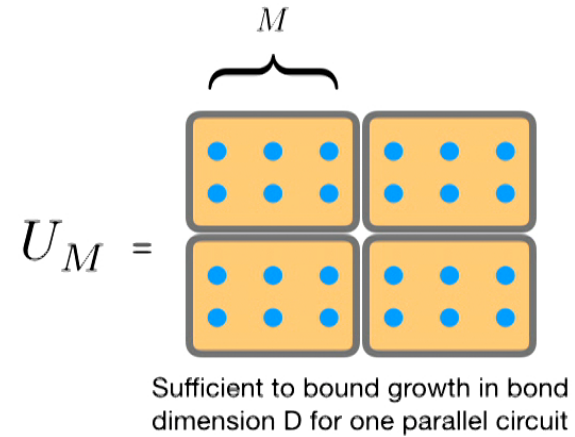

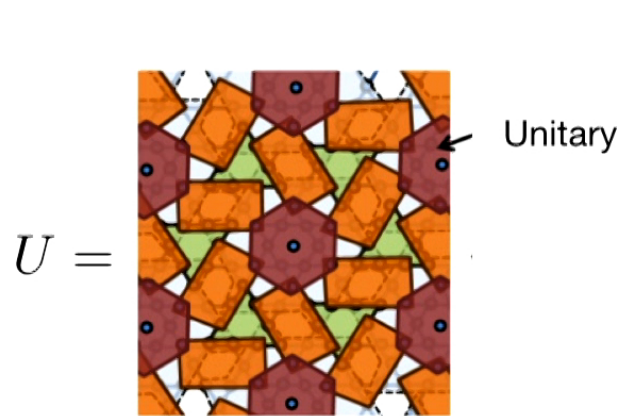

1) Course-graining move

2) Onsite-unitary move (preserves iso-TNS)

3) Fine-graining move

If $|\Phi\rangle$ is iso-TNS, and U is finite-depth circuit, then $U|\Phi\rangle$ has exact iso-TNS form

1) Course-graining move

2) Onsite-unitary move (preserves iso-TNS)

3) Fine-graining move

Bad / stupid bound,
but establishes principle:

$$D \rightarrow D^M d^{M^2/2}$$

spin size

Variational power: future questions

Let $|\psi\rangle$ be target state and $|\psi_D\rangle$ a rank-D isoTNS approximation. What entanglement properties of $|\psi\rangle$ are sufficient to bound the error $\| |\psi\rangle - |\psi_D\rangle \|^2$?

Variational power: future questions

Let $|\psi\rangle$ be target state and $|\psi_D\rangle$ a rank-D isoTNS approximation. What entanglement properties of $|\psi\rangle$ are sufficient to bound the error $\| |\psi\rangle - |\psi_D\rangle \|^2$?

1D: the Renyi Entropy $S^{(n)}$. If 1D bipartite entanglement is bounded by $S^{(n)}$,

$$\| |\psi\rangle - |\psi_D\rangle \|^2 / L \leq \left(\frac{1-n}{D} \right)^{\frac{1-n}{n}} e^{\frac{1-n}{n} S^{(n)}}, \quad n < 1$$

[Verstraete & Cirac, 2005]

Establishes linear-L difficulty for area-law phases and poly(L) for CFTs

Variational power: future questions

Let $|\psi\rangle$ be target state and $|\psi_D\rangle$ a rank-D isoTNS approximation. What entanglement properties of $|\psi\rangle$ are sufficient to bound the error $\| |\psi\rangle - |\psi_D\rangle \|^2$?

1D: the Renyi Entropy $S^{(n)}$. If 1D bipartite entanglement is bounded by $S^{(n)}$,

$$\| |\psi\rangle - |\psi_D\rangle \|^2 / L \leq \left(\frac{1-n}{D} \right)^{\frac{1-n}{n}} e^{\frac{1-n}{n} S^{(n)}}, \quad n < 1$$

[Verstraete & Cirac, 2005]

Establishes linear-L difficulty for area-law phases and poly(L) for CFTs

2D: bipartite entanglement certainly won't be enough! [Ge & Eisert, 2016]

Hierarchy (?) of area-law states: gapped, non-chiral < gapped, chiral < gapless CFT < ground states < area law <

What are entanglement distinctions between area-law phases, and how do they lead to different TNS accuracy?

Extremely difficult question for generic PEPs, but the isometry condition may make iso-TNS much more tractable to analyze

- 1) The isometric TNS variational ansatz
- 2) Variational power of isoTNS
- 3) **Algorithms:** Moses Move, TEBD², DMRG²

How do we move the orthogonality center?

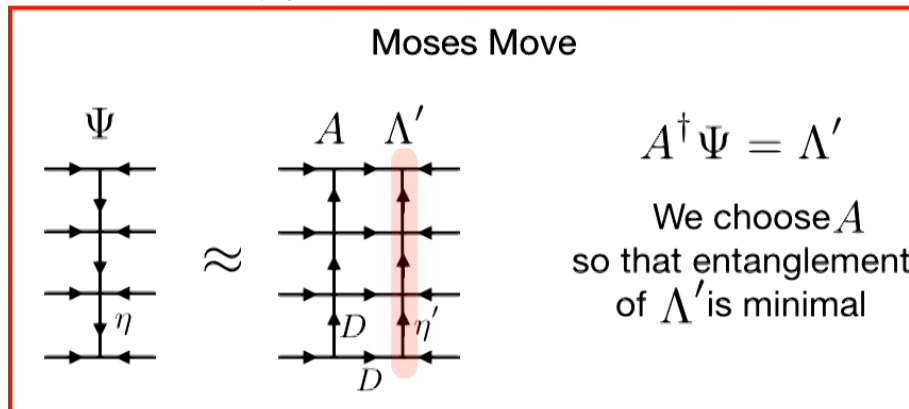

For 1D MPS:

Any orthogonal decomposition
of a matrix will do: $(\Lambda B) = QR = U(sV) = \dots$

We can use this (unitary) ambiguity to fix various properties of Λ'

First group columns
together into a can. MPS Ψ

Caveat: unless $\eta' = D\eta$, MM is approximate, so eventually make small errors

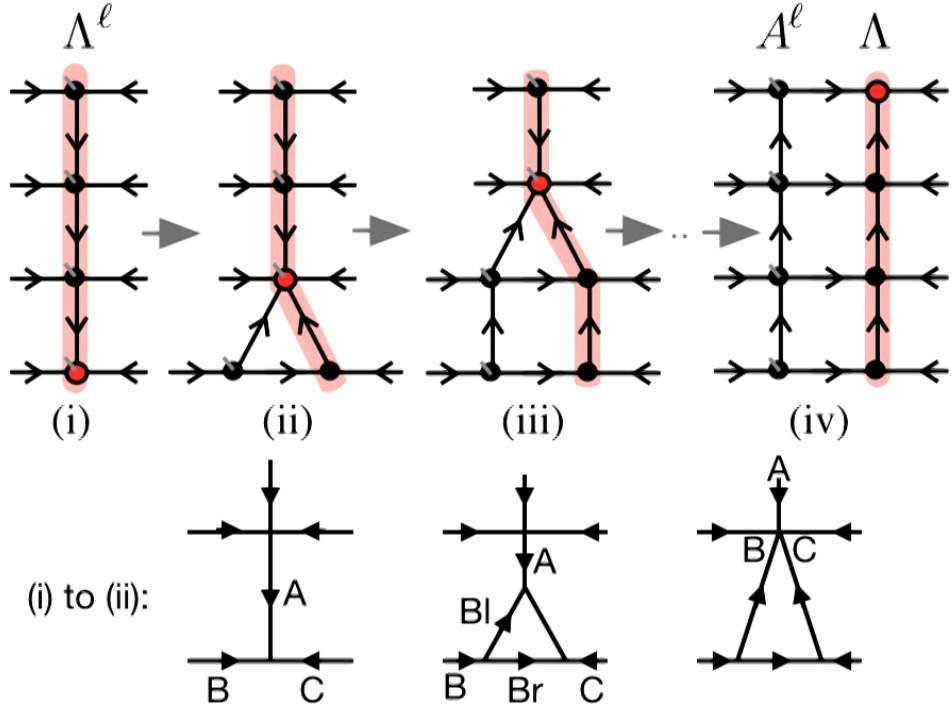

Moses Move

[Thanks to R. Mong for name!]

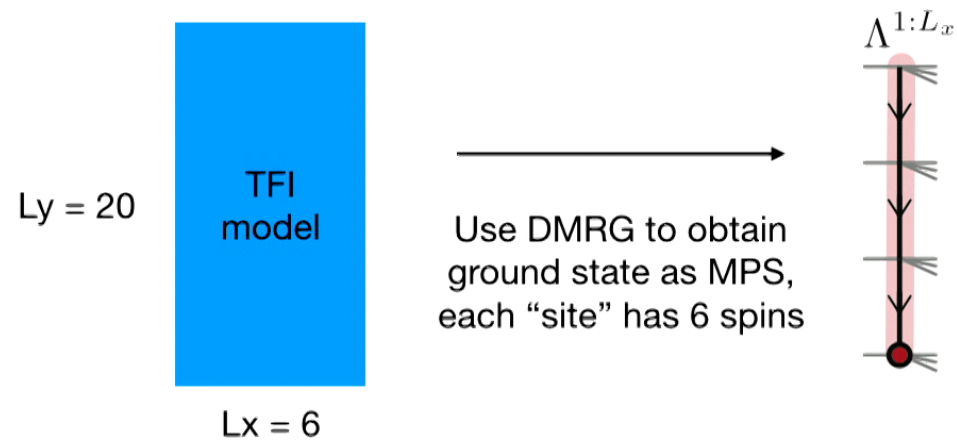

Let me unpack this...

Moses Move

Testing the Moses Move: MPS to isoTNS

Suppose we are *given* a 2D wavefunction :
can we use MM to iteratively put it in isoTNS form?

(I want to separate out *finding* ground state
from *representing* ground state)

Entanglement reduction

TEBD²

First review:

TEBD¹
[Vidal 2003]

$$e^{-tH} |0\rangle = \prod_j e^{-\Delta t H_j} |0\rangle$$

↓ MPS compression
↓ MPS compression
↓ MPS compression
↓ MPS compression

Orthogonality center sweeps
back & forth with trotterization,
ensuring local SVD truncation
is globally optimal

TEBD² Trotterization

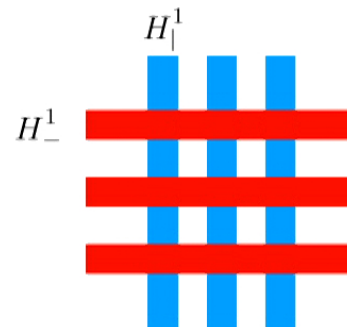

$$H = \sum_c H_{|}^c + \sum_r H_{-}^r$$

Split into columns & rows
(assume nearest-neighbor H)

$$H_{|}^c = \sum_r h_{|}^{c,r}$$

$$H_{-}^r = \sum_c h_{-}^{c,r}$$

Each column / row has own
1D trotterization

$$\dots \prod_r e^{-dt H_{-}^r} \prod_c e^{-dt H_{|}^c} |0\rangle$$

TEBD²

Start in this form:

$\Lambda^{[1]} \quad B^{[2]} \dots$

TEBD²

Start in this form:

Now apply $e^{-dt H_1^1}$ by *literally* calling 1D TEBD on $\Lambda^{[1]}$

$$e^{-d\tau H_1^1} |\Lambda^{[1]}\rangle = \text{Diagram}$$

$e^{-d\tau H_{\text{bond}}}$

No environments, “full update,” or other complications.

TEBD²

Start in this form:

Now apply $e^{-dtH_1^1}$ by *literally* calling 1D TEBD on $\Lambda^{[1]}$

No environments, “full update,” or other complications.

Then MM over ortho-center, and apply $e^{-dtH_1^2}$

TEBD²

After columns, tilt head 90° and apply rows:

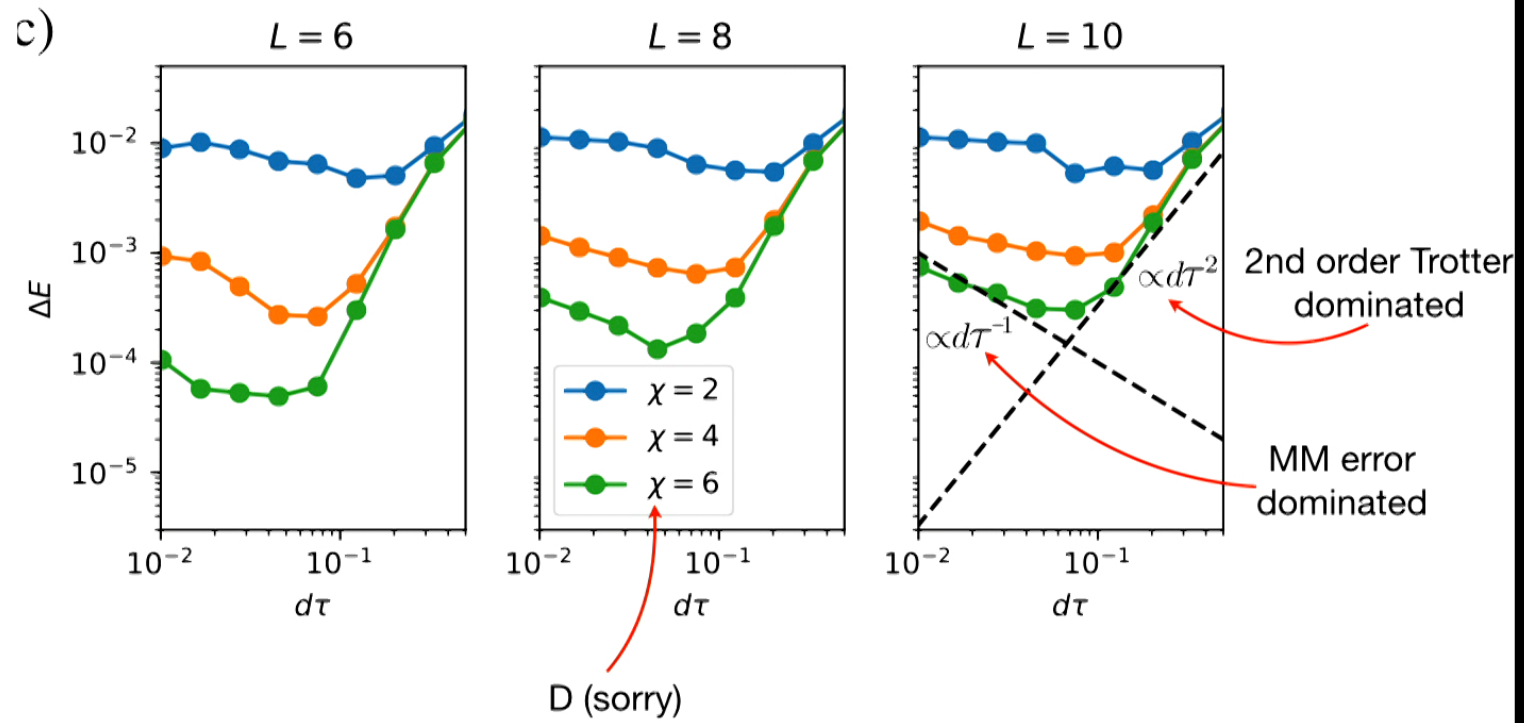

COST:

$$\text{isoTNS TEBD}^2: \mathcal{O}(\eta^3 D^3 + D^6)$$

$$\text{TNS Full-update w/ boundary MPS: } \mathcal{O}(\eta^3 D^4 + \eta^2 D^6 + D^{12})$$

Error in TFI energy ($g = 3.5$)

DMRG²

Call 1D DMRG for each column (“inner sweep”)
sweep left / right between columns using MM (“outer sweep”)

$$\text{DMRG}^2 = \text{DMRG} \otimes \text{DMRG}$$

Trickier to implement than TEBD because
need Hamiltonian terms... but testing now

Thanks!
