Single Photon Detectors

Sae Woo Nam

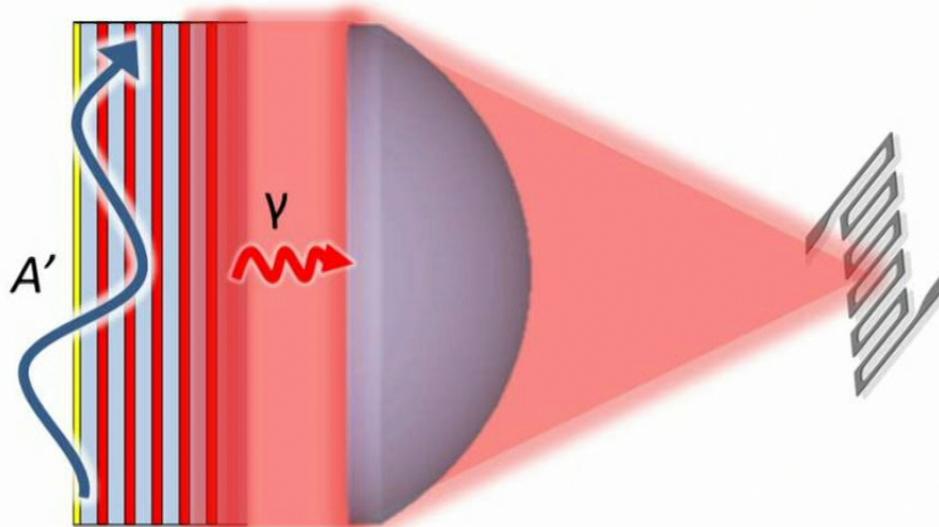

NIST - National Institute of Standards and Technology

Outline

- Lecture 2: Building LAMPOST
 - Cryogenics
 - Electronics
 - Optics
 - Detectors
 - Taking Data
 - What's next?
 - Veto backgrounds
 - Calibrations

LAMPOST: Dark Photons

- Absorb dark photon, convert to standard photon

- Requirements for Photon Detector:
 - Very low dark counts (false positives)
- Cryogenic Detectors:
 - SNSPD vs TES
 - SNSPD is simpler to use

Cryogenics / Cryostat

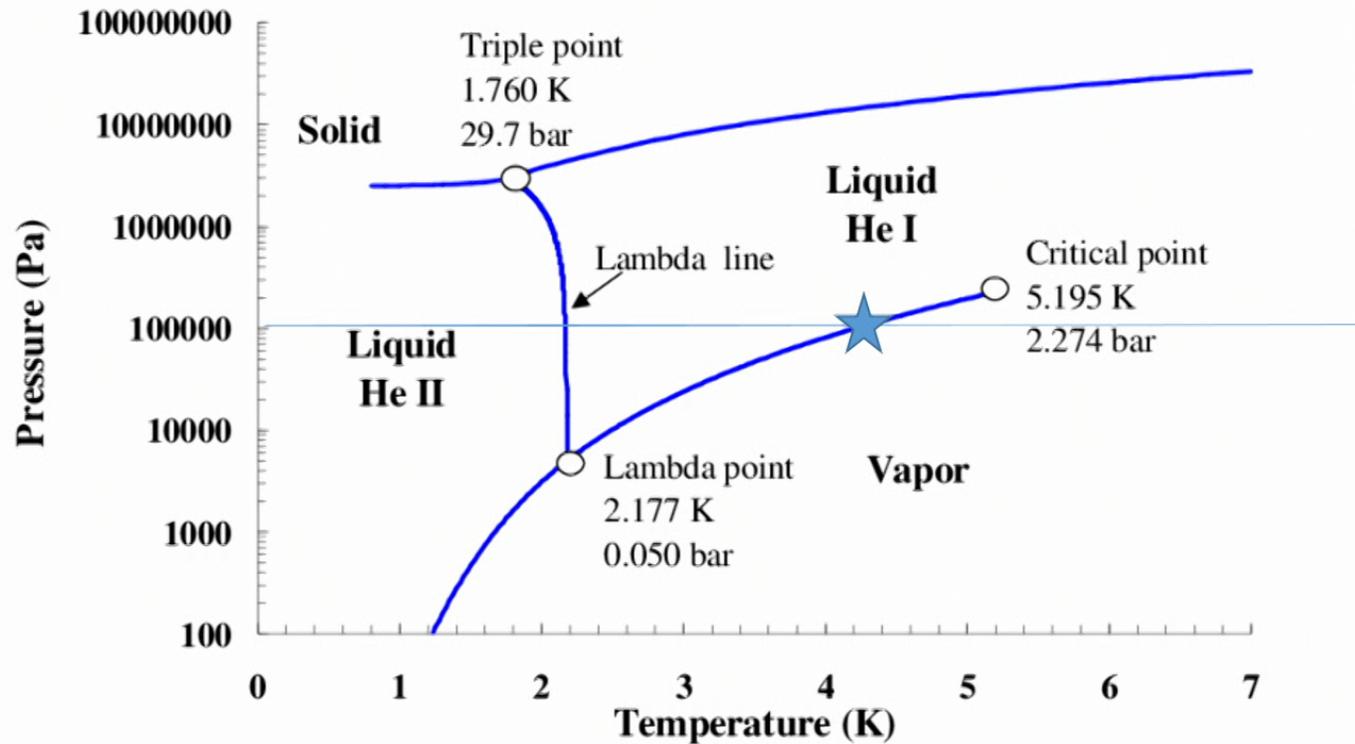

- Temperature as cold as possible, but easy to maintain
 - Target: 300 mK
- How do you get cold? Thermodynamic Properties
- How do you create an environment that holds cold stuff?
...Mechanical Engineering
 - Sources of Heat
 - Materials

Properties of Gases

Cryogen	Triple point [K]	Normal boiling point [K]	Critical point [K]
Methane	90.7	111.6	190.5
Oxygen	54.4	90.2	154.6
Argon	83.8	87.3	150.9
Nitrogen	63.1	77.3	126.2
Neon	24.6	27.1	44.4
Hydrogen	13.8	20.4	33.2
Helium	2.2 (*)	4.2	5.2

Gifford-McMahon Cooler

Cooling Power Specifications

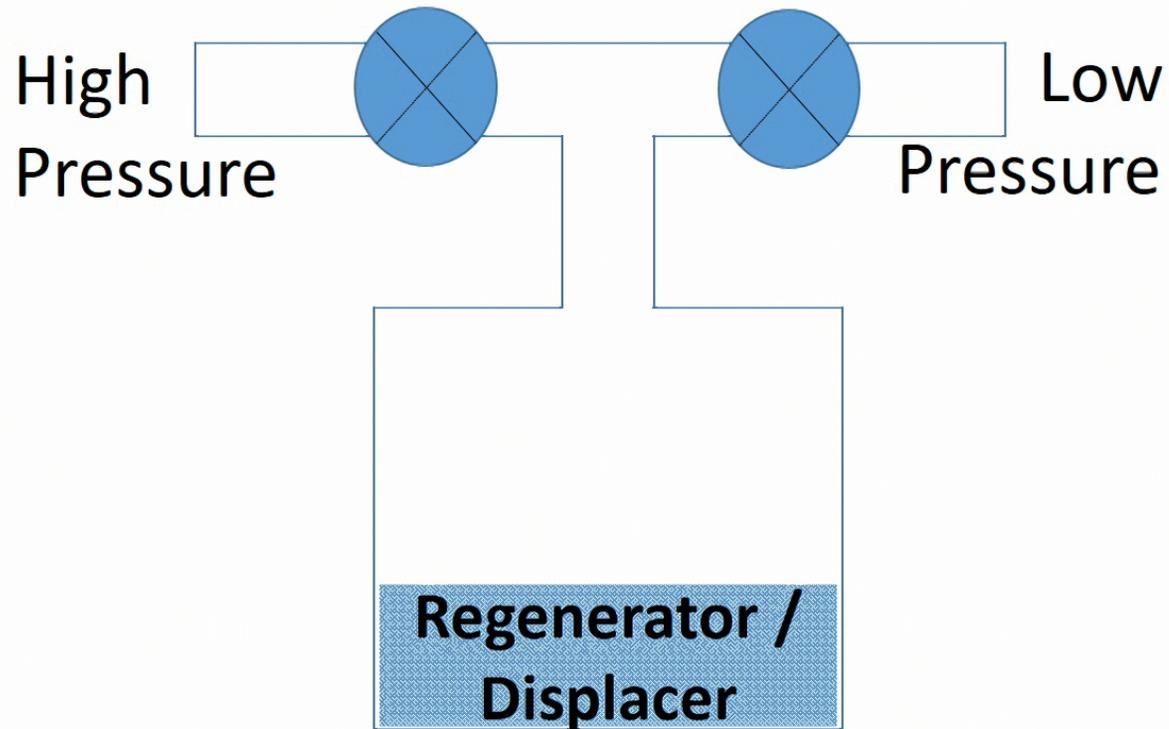

@60K: 5 Watts

@4.2K: 100mW

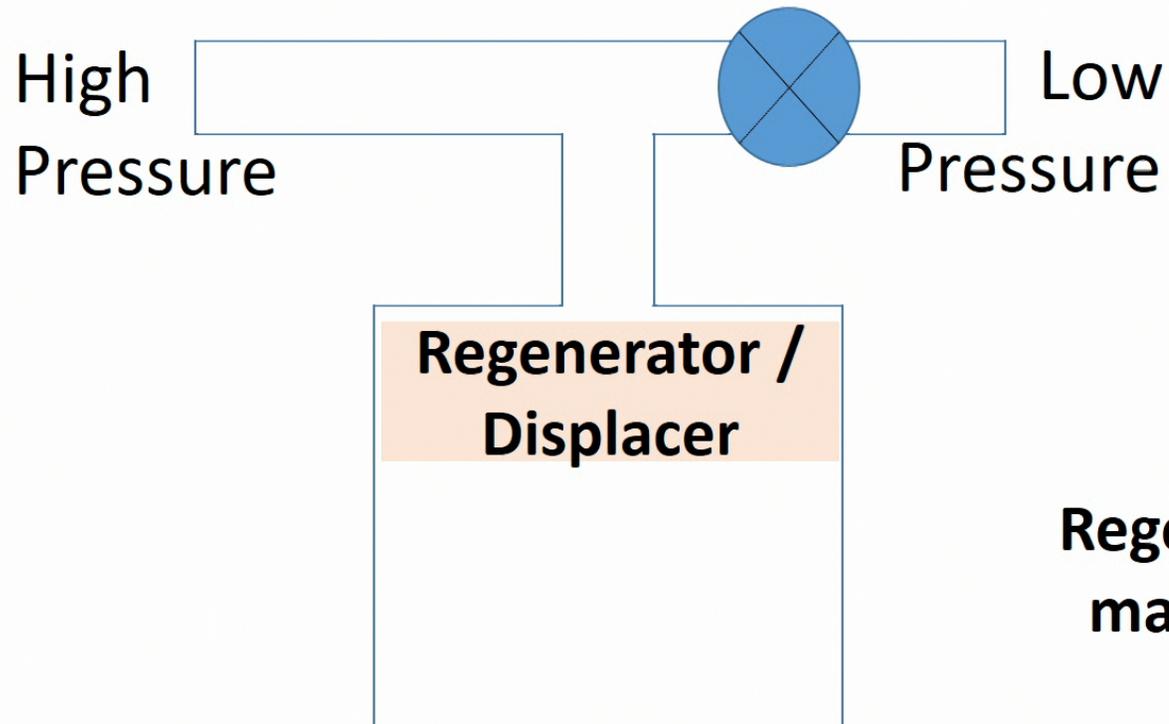

Requires a Helium compressor (1.5kW)

• [IOP Conference Series Materials Science and Engineering](#) 101(1):012136

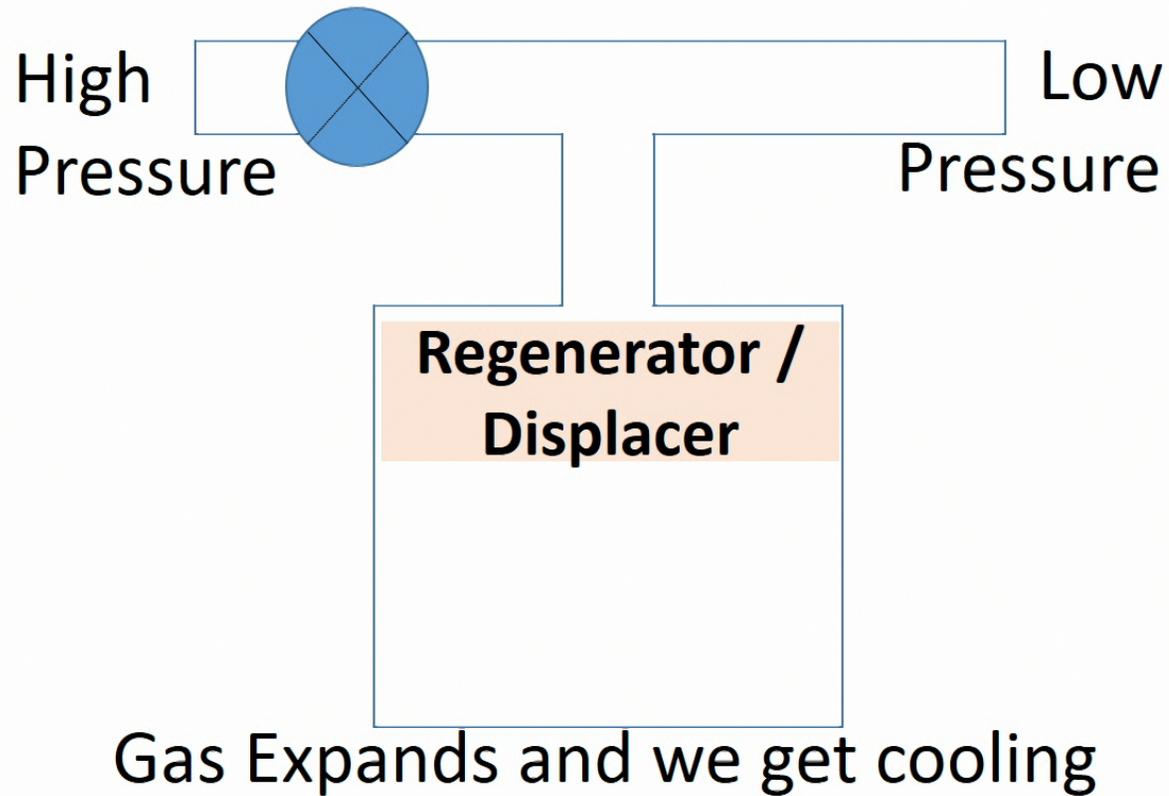

GM-cooling (simple pictures):

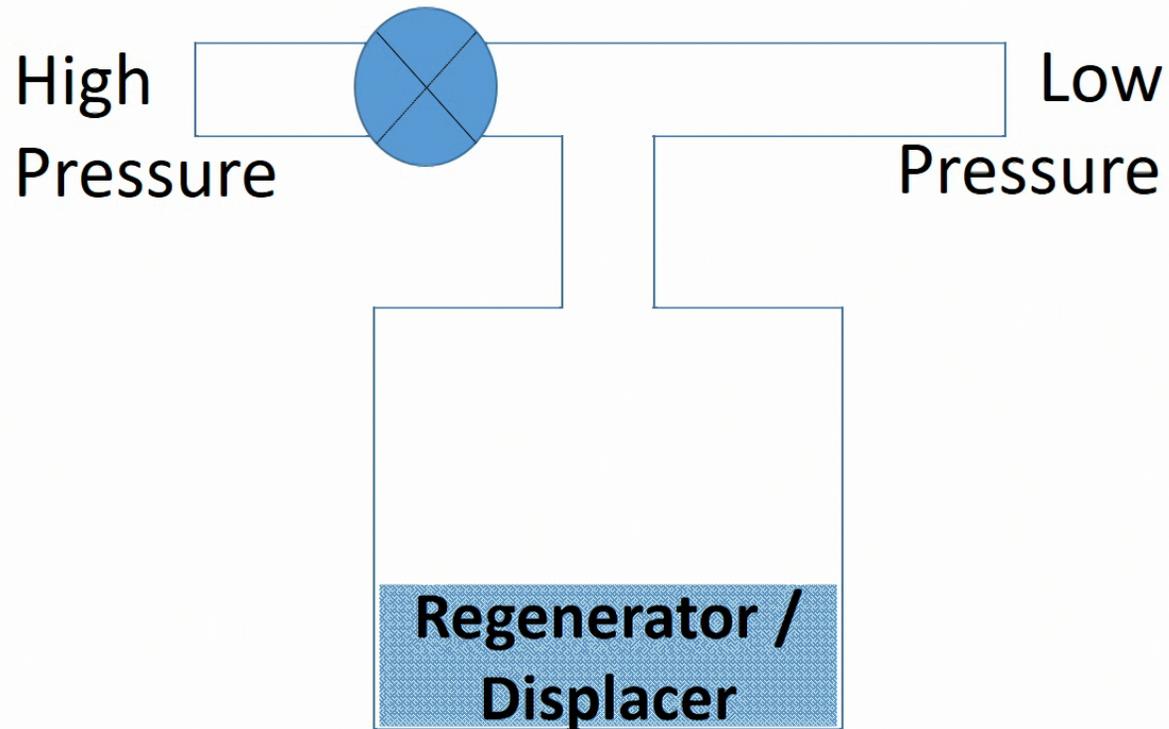

GM-cooling (simple pictures):

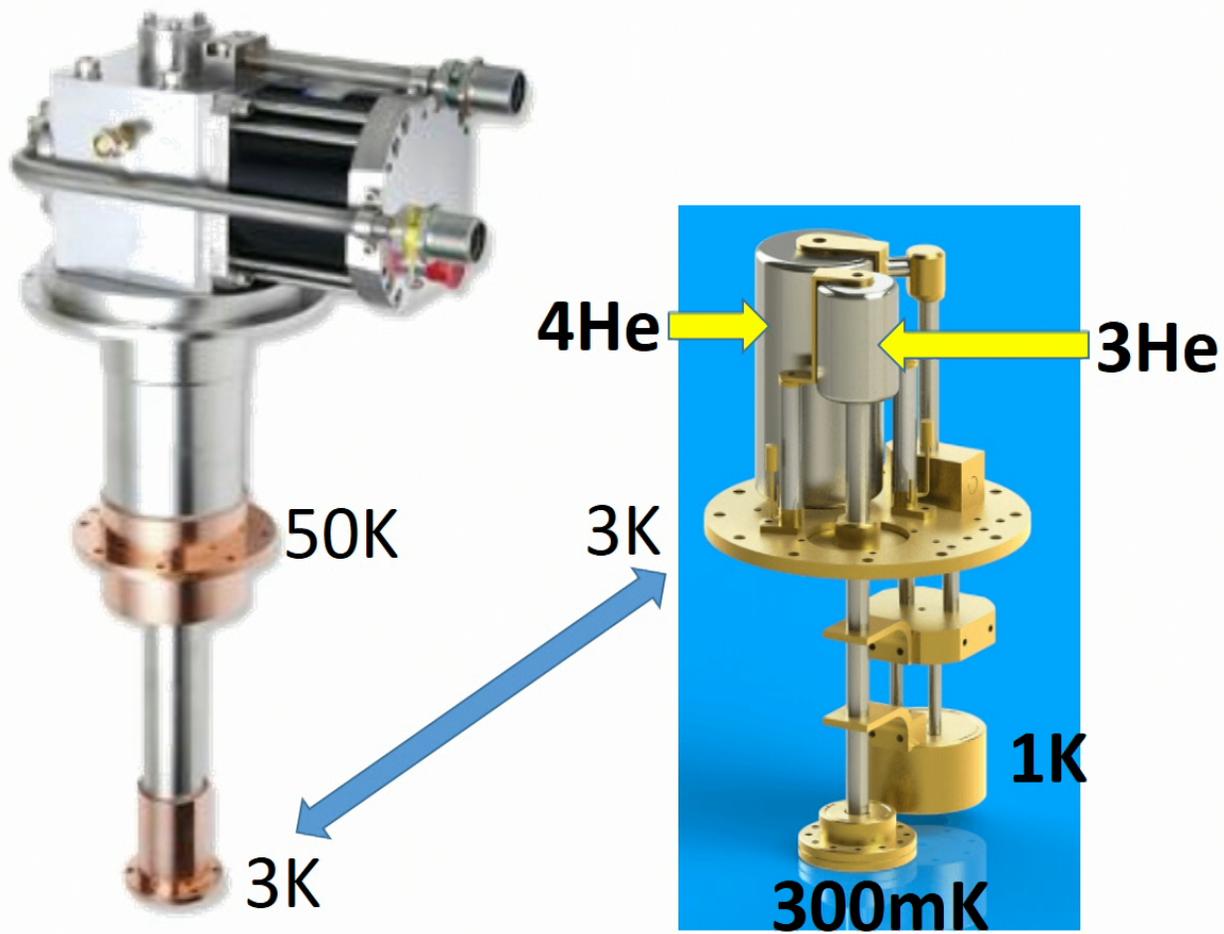

GM-cooling (simple pictures):

GM-cooling (simple pictures):

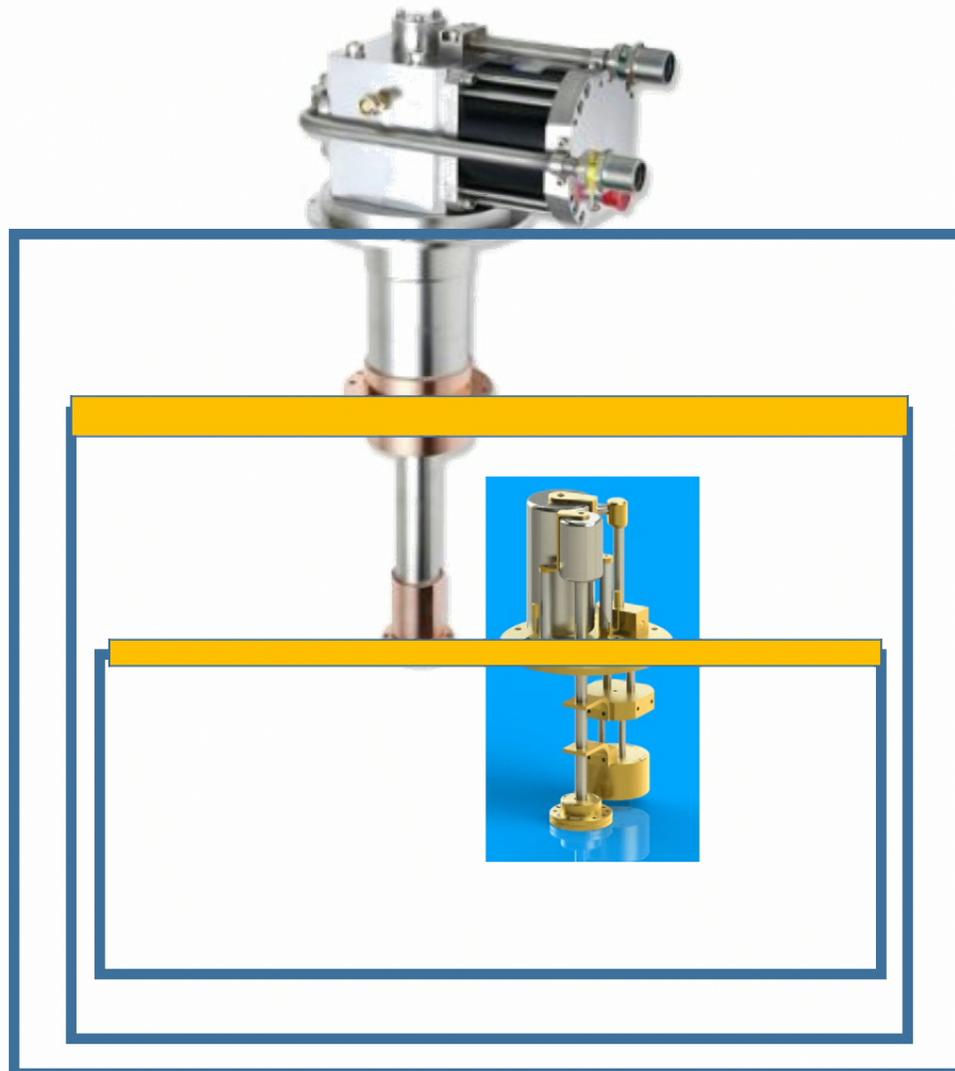

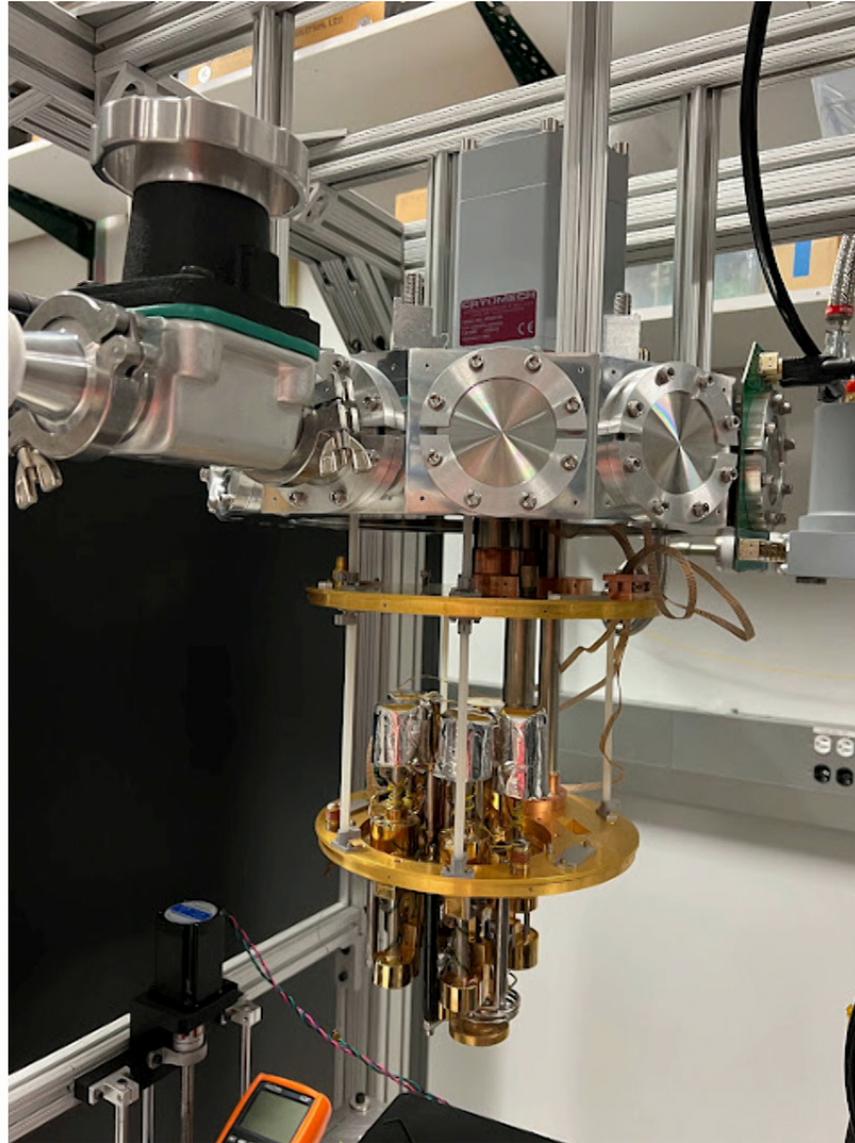

How do you hold the refrigeration together?

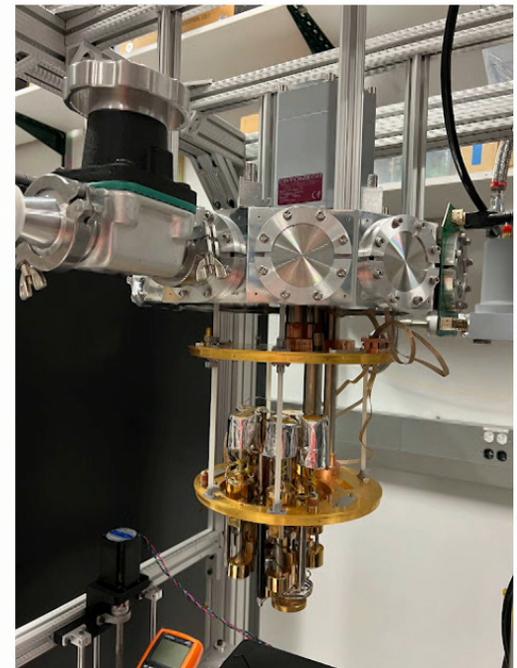

- We do not have infinite cooling power....
 - Reduce sources of heat as much as possible
 - Vacuum
 - Radiation
 - Thermal conduction (materials we can use)

Fits in a standard
instrumentation rack

How do we know the temperature?

- 300K to 2K.... Diode thermometers
- 1K and lower: Resistive thermometers
- How much heat does wiring add?
 - We can estimate using Fourier's Law and Wiedemann-Franz Law

$$\dot{Q} = -k(T)A\nabla T$$

$$k(T) = \mathcal{L}T\sigma = \frac{\mathcal{L}T}{\rho}$$

$$\mathcal{L} = 24.4 \frac{nW\Omega}{K^2}$$

Heatload from a wire

$$\dot{Q} = -k(T)A\nabla T$$

$$k(T) = \mathcal{L}T\sigma = \frac{\mathcal{L}T}{\rho}$$

Assume resistance is not
Temperature dependent

$$\dot{Q} = \mathcal{L} \frac{A}{\rho l} \frac{T_{hot}^2 - T_{cold}^2}{2}$$

$$\dot{Q} = -\mathcal{L}T \frac{A dT}{\rho dx}$$

$$\int_0^l \dot{Q} dx = - \int_{T_{hot}}^{T_{cold}} \mathcal{L}T \frac{A dT}{\rho}$$

$$\dot{Q}l = \mathcal{L} \frac{A}{\rho} \int_{T_{cold}}^{T_{hot}} T \frac{dT}{dx}$$

$$\dot{Q} = \mathcal{L} \frac{T_{hot}^2 - T_{cold}^2}{2R}$$

Heatload from a wire

$$\dot{Q} = \mathcal{L} \frac{T_{hot}^2 - T_{cold}^2}{2R}$$

T_hot = 300K, T_cold = 50K, R=1

Heatload = 24.4 nW * 300² = 2.2 mW

T_hot = 50K, T_cold = 4K, R=1

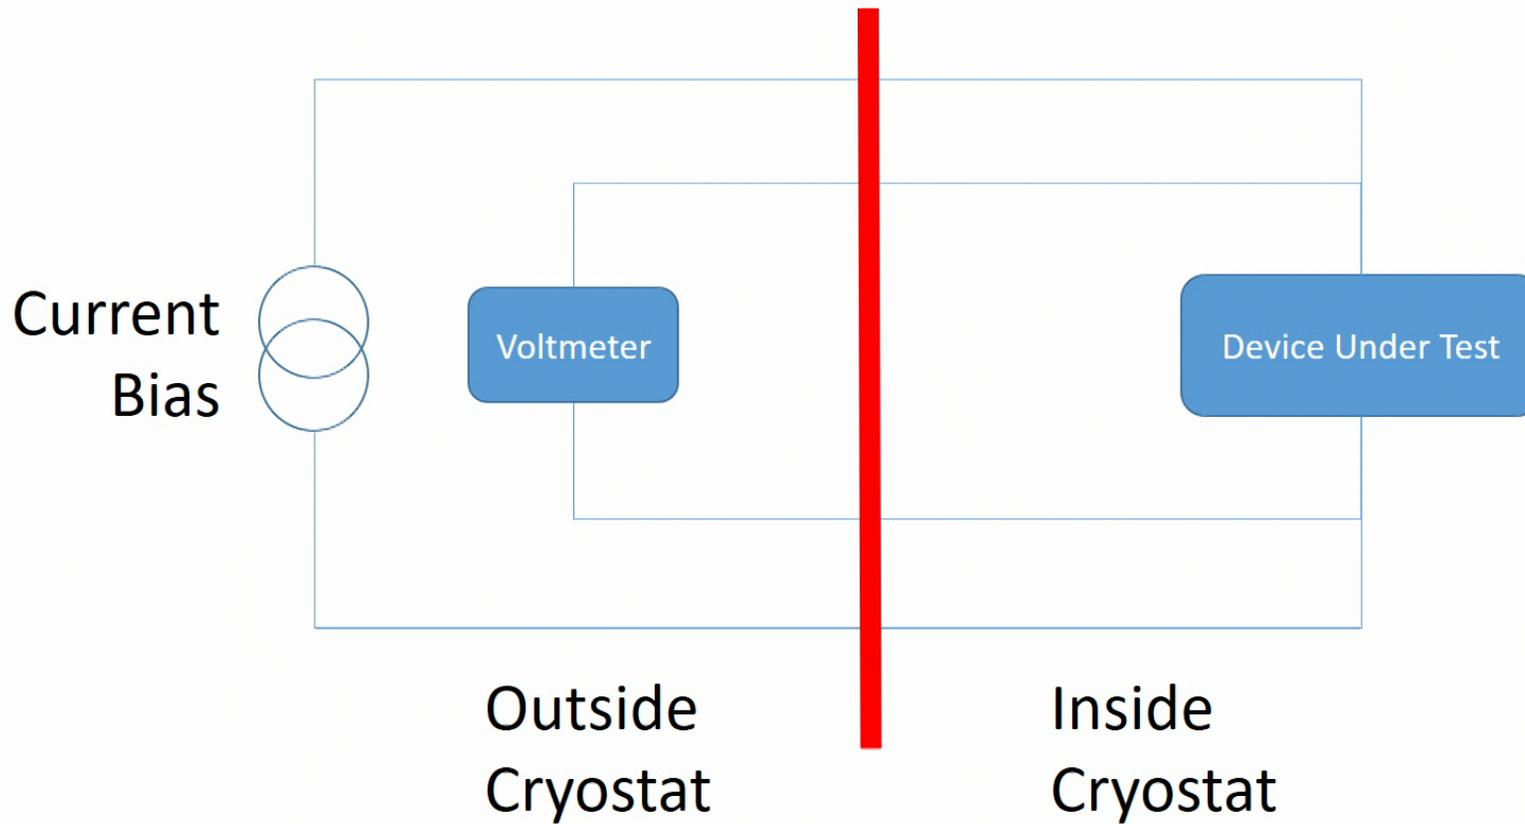

Heatload = 24.4nW * 50² = 61 μW

Measuring Temperature:

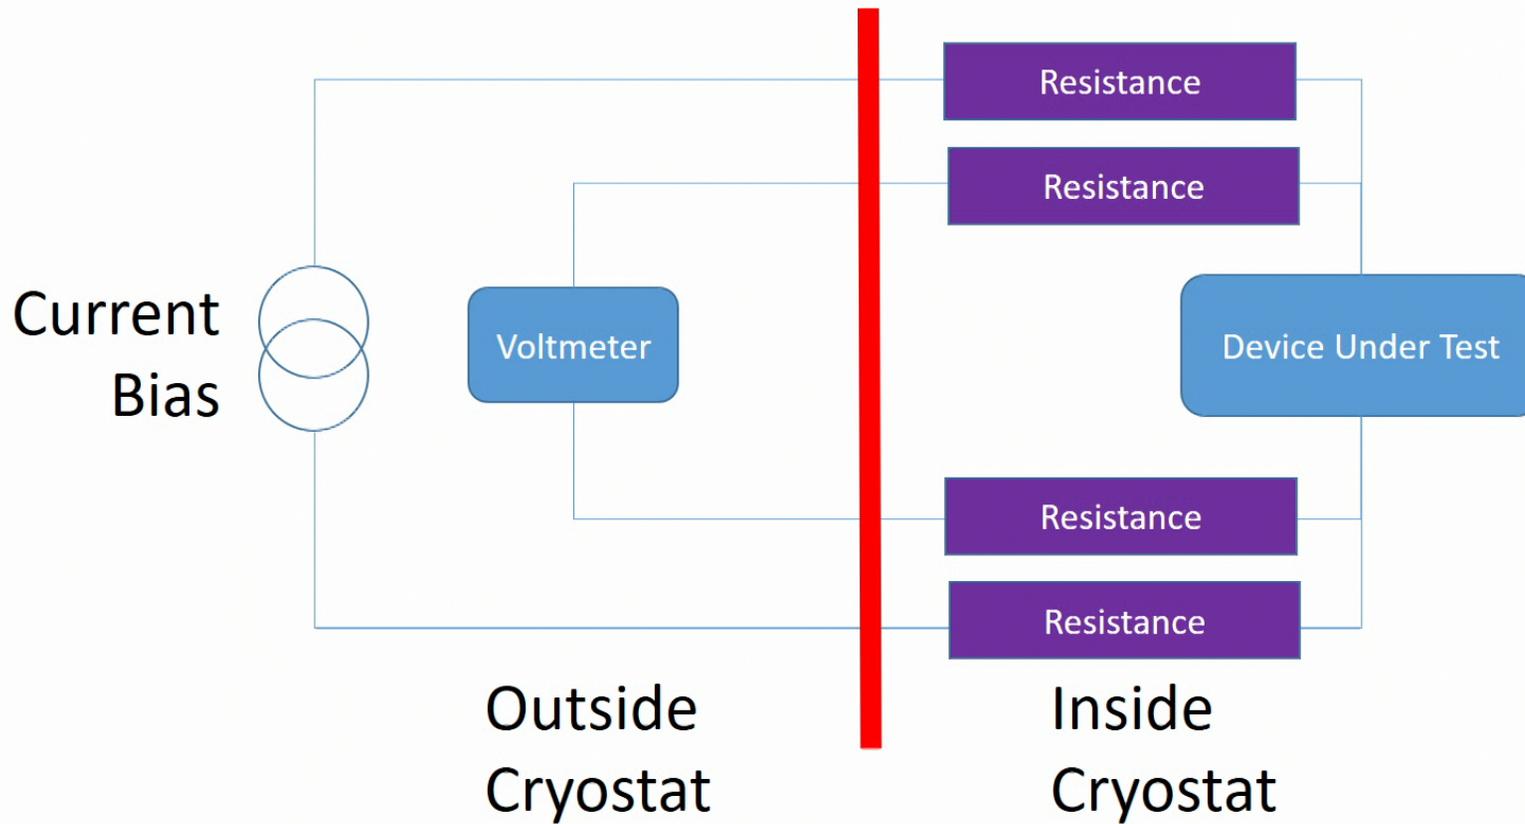

- Diodes:
 - Bias at a fixed current, measure voltage...
- Resistors:
 - Temperature dependence
- Four wire technique:
 - Why?

$$I_D = I_o \left(e^{\frac{qV_D}{nkT}} - 1 \right)$$

Four-Wire measurements

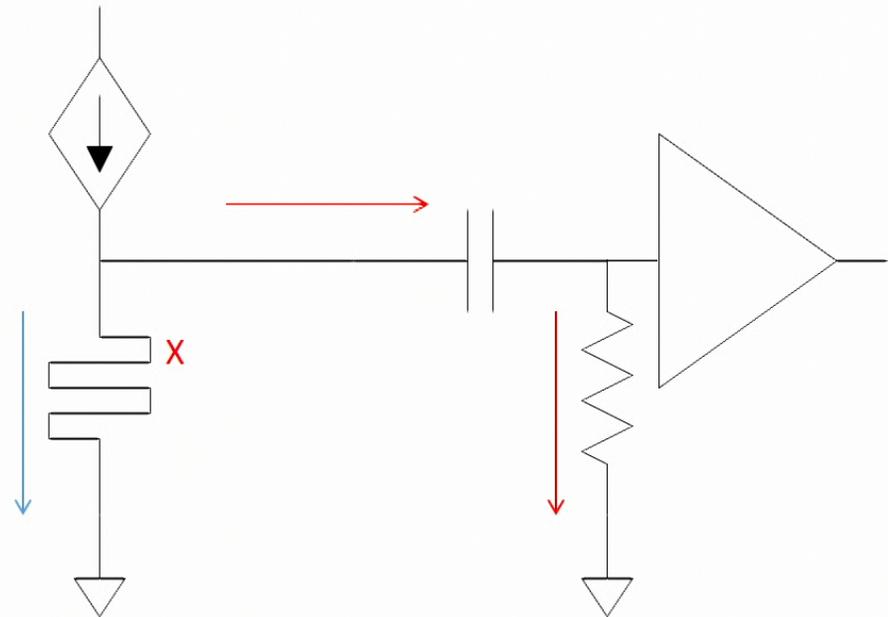

Four-Wire measurements

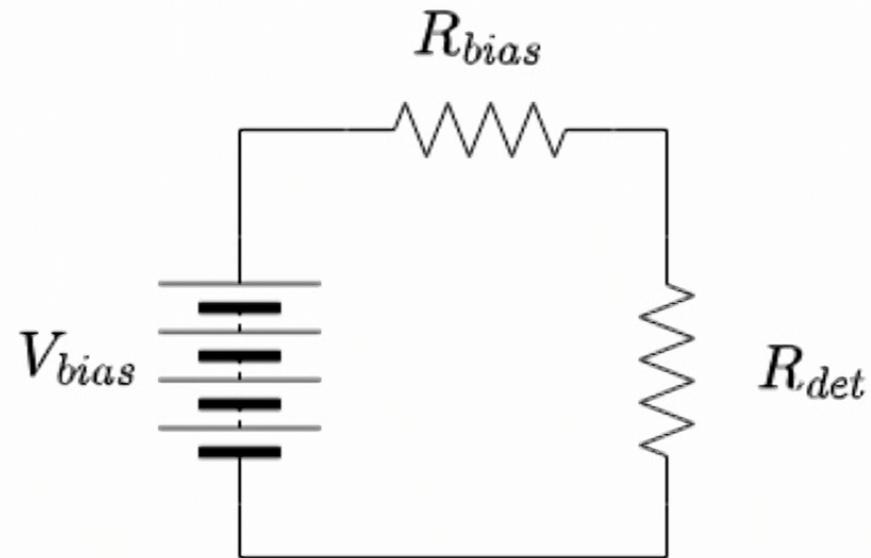

Detector Electronics

- Detector Bias
- RF-amplifier

Current Bias:

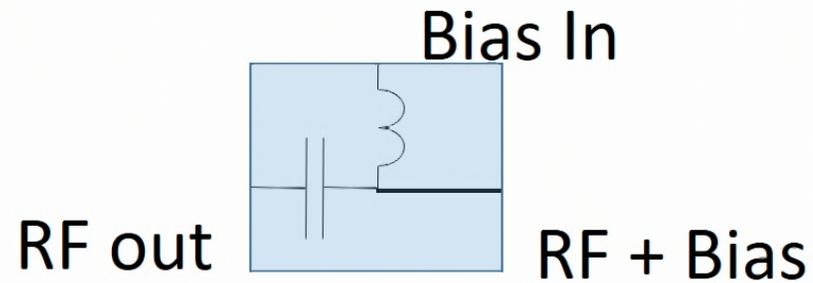

- KISS
- Simple and approximate

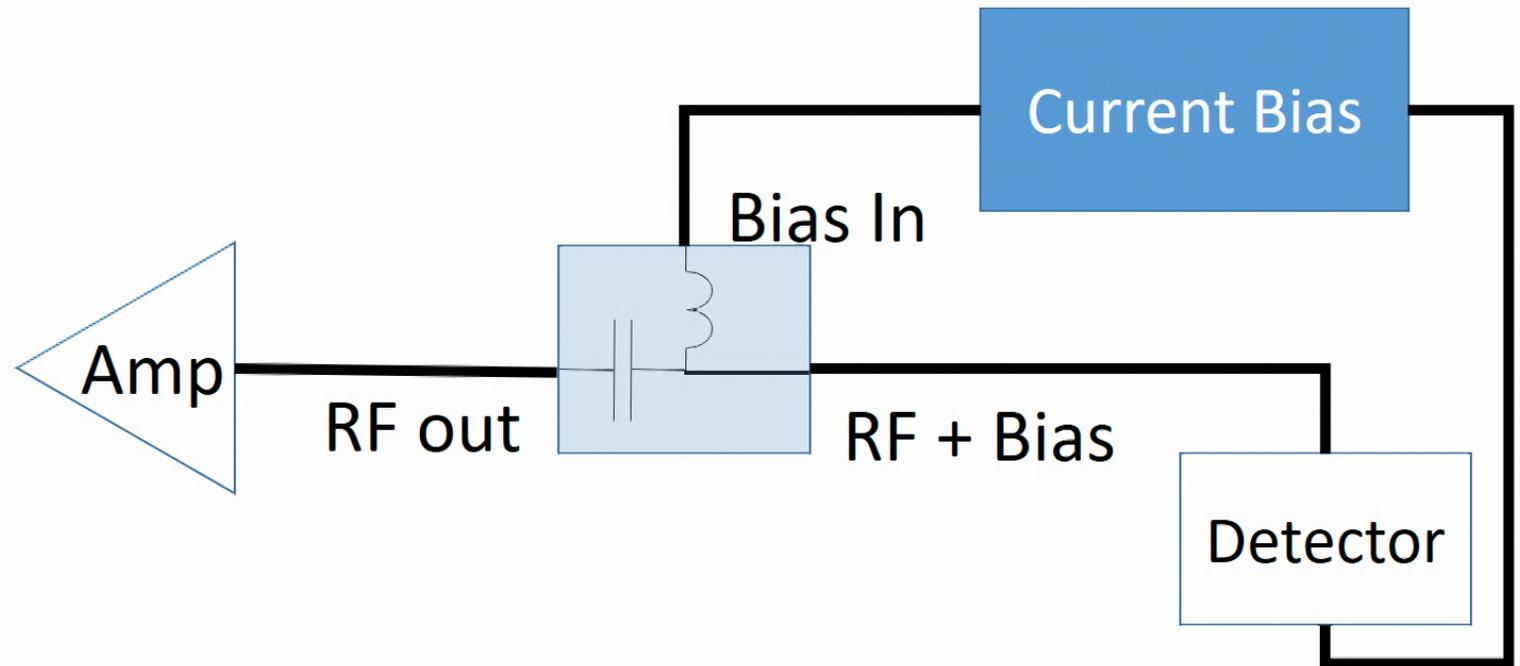

$$I_{bias} = \frac{V_{bias}}{R_{bias} + R_{det}} = \frac{V_{bias}}{R_{bias} \left(1 + \frac{R_{bias}}{R_{det}}\right)}$$

Bias + signal from the detector:

- “BIAS TEE”
- Three Terminal device

More complete circuit for the detector

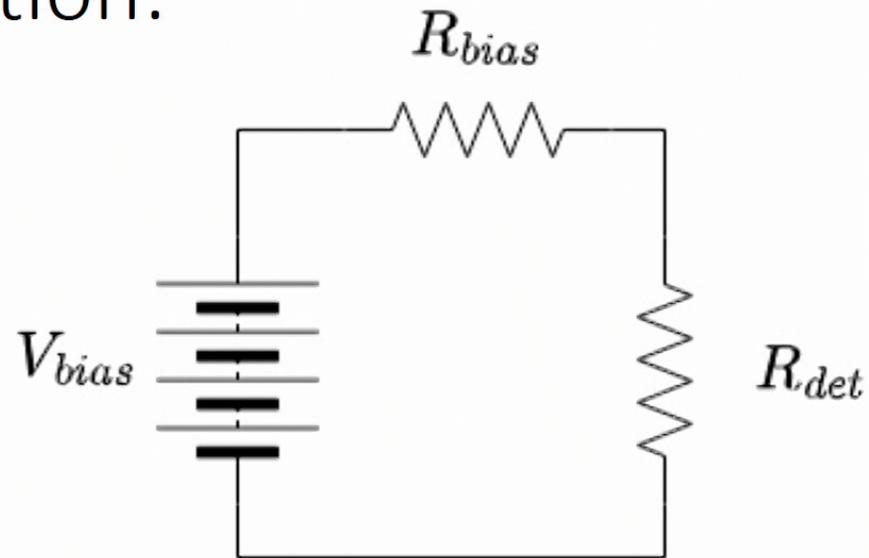

How much current noise comes from the bias circuit?

- We don't live in an environment where the temperature = 0.
- We need a few microamps of current to bias the nanowire detector.
 - The current source will introduce noise/fluctuations in the bias current.
 - How much will this fluctuation be?

Need more information:

- V_{bias} noise $\sim 10\text{nV}/\text{rtHz}$
- Bias Tee filters the noise
 - Bandwidth = 100kHz
- $R_{bias} \sim 100\text{ k}\Omega$

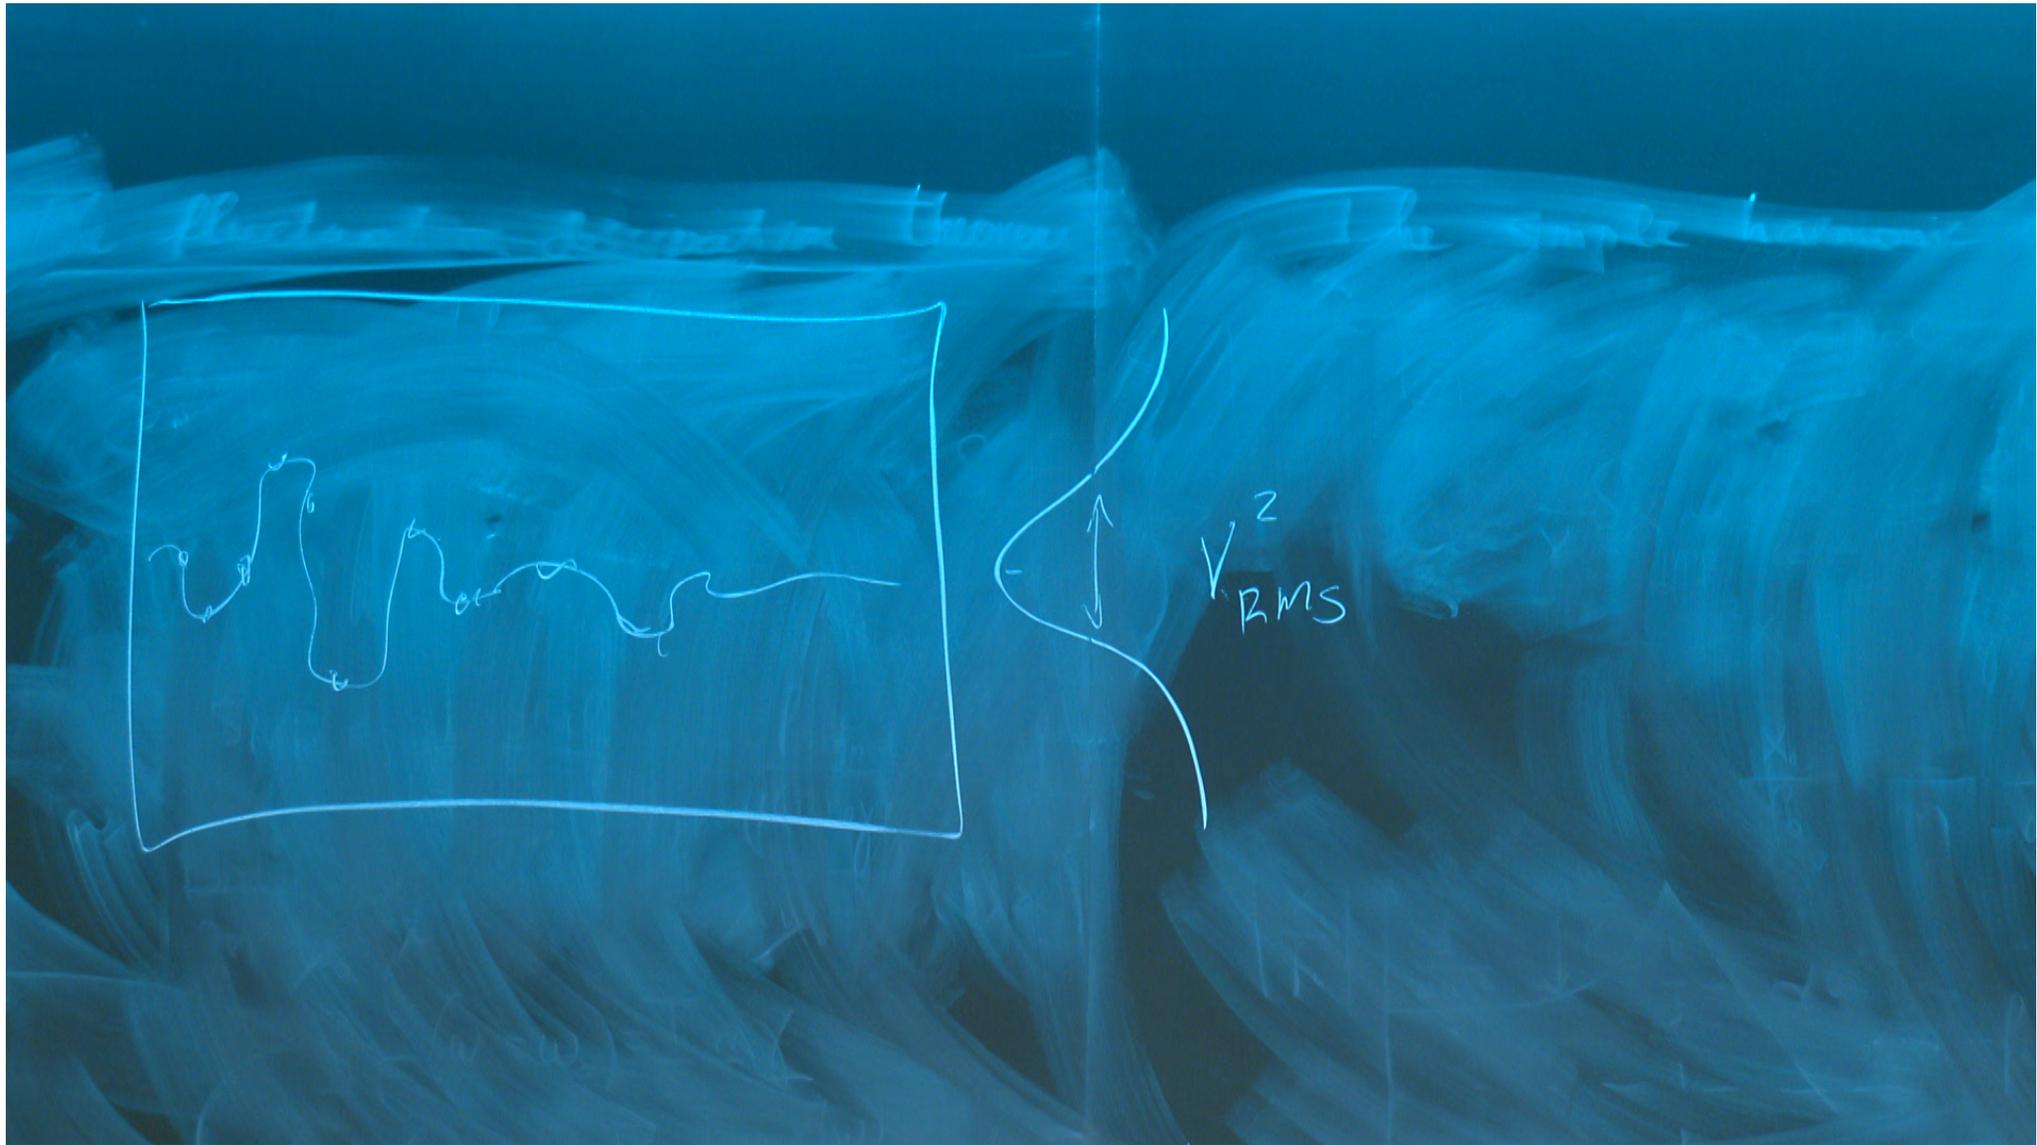

Comments about Noise

- Noise is unpredictable in amplitude and phase
- “60Hz” pickup... => not “random noise”
- Random noise:
 - Quantify by looking at the $\langle \text{noise}^2 \rangle$ because $\langle \text{noise} \rangle = 0$

$$\langle n^2 \rangle = \frac{1}{T} \int_0^T n(t)^2 dt$$

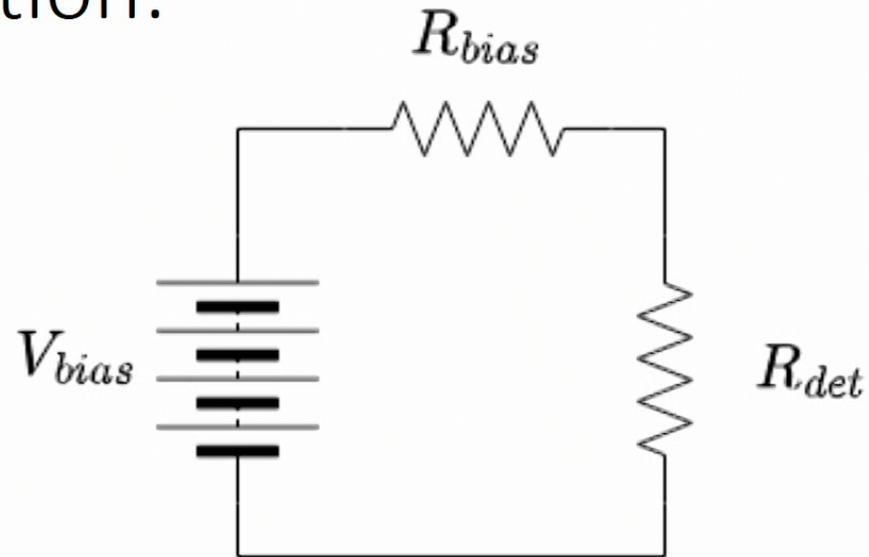

- Parseval's Theorem:

$$\langle n^2 \rangle = \frac{1}{T} \int_0^T n(t)^2 dt = \int \|\mathcal{N}(f)\|^2 df$$

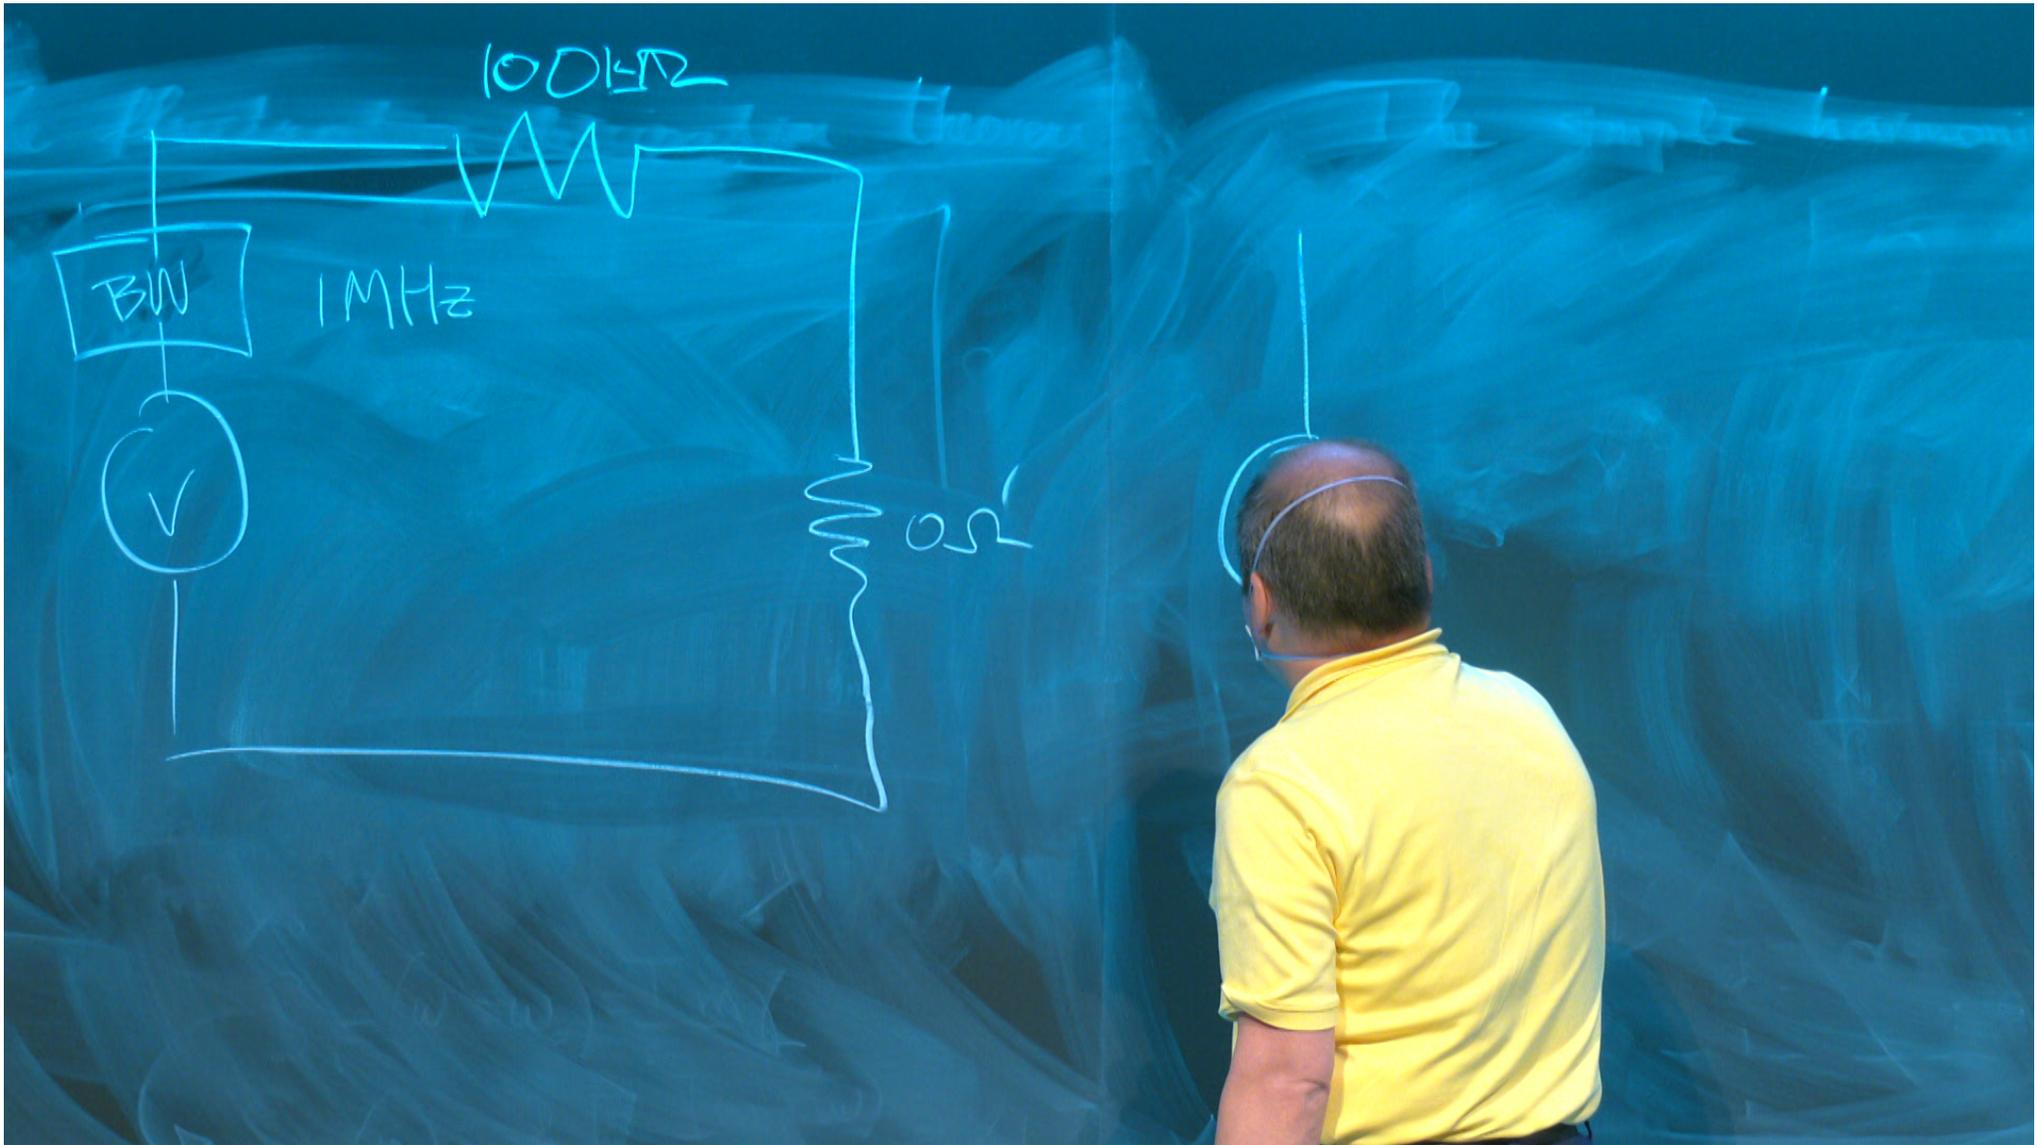

Need more information:

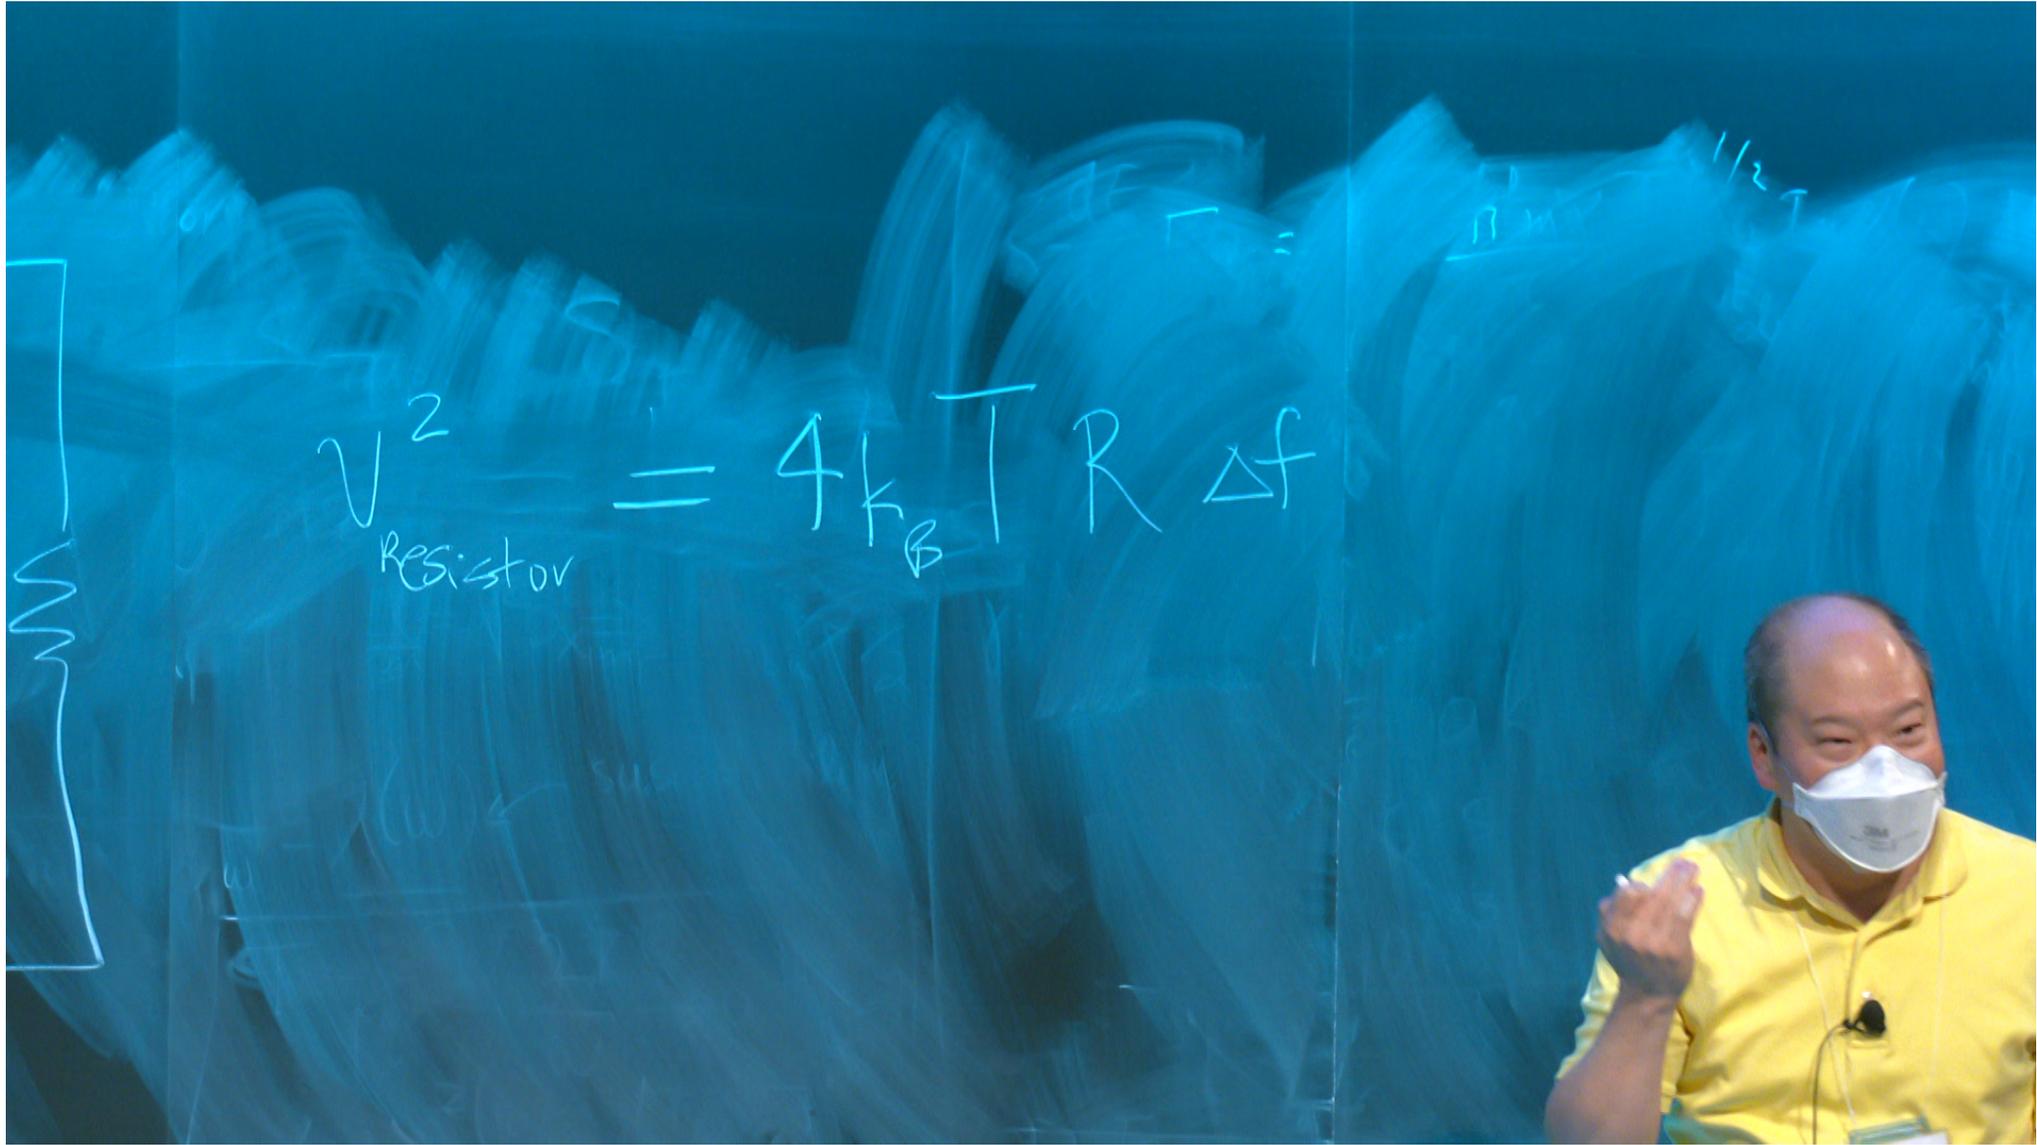

- V_{bias} noise $\sim 10\text{nV}/\text{rtHz}$
- Bias Tee filters the noise
 - Bandwidth = 100kHz
- $R_{bias} \sim 100\text{ k}\Omega$

$$10 \text{ nV} \sqrt{\text{Hz}} \sqrt{10^6 \text{ Hz}} = 10 \text{ } \mu\text{V}_{\text{RMS}}$$

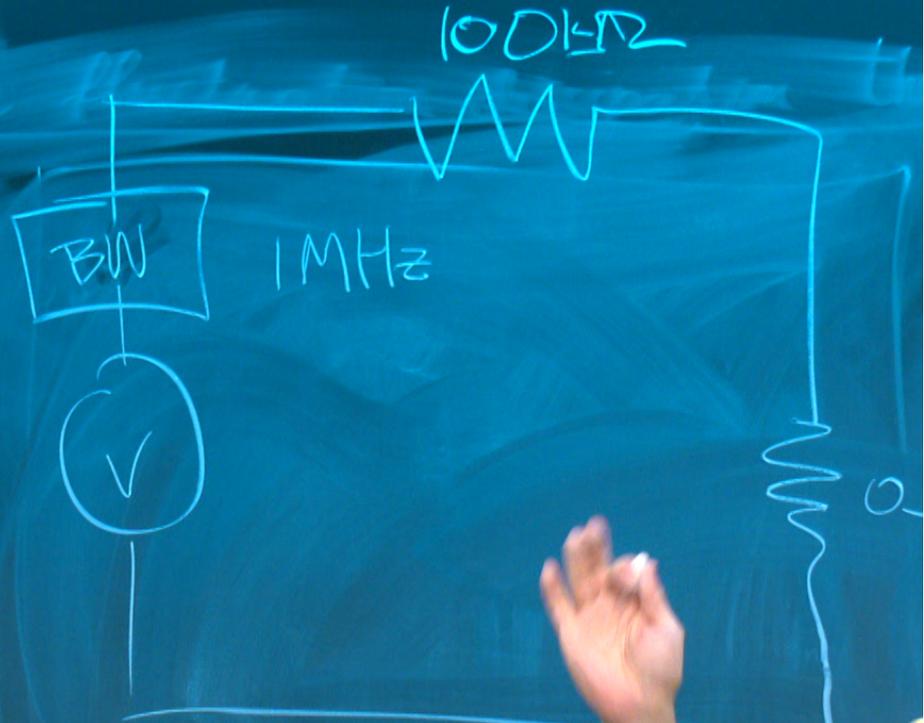

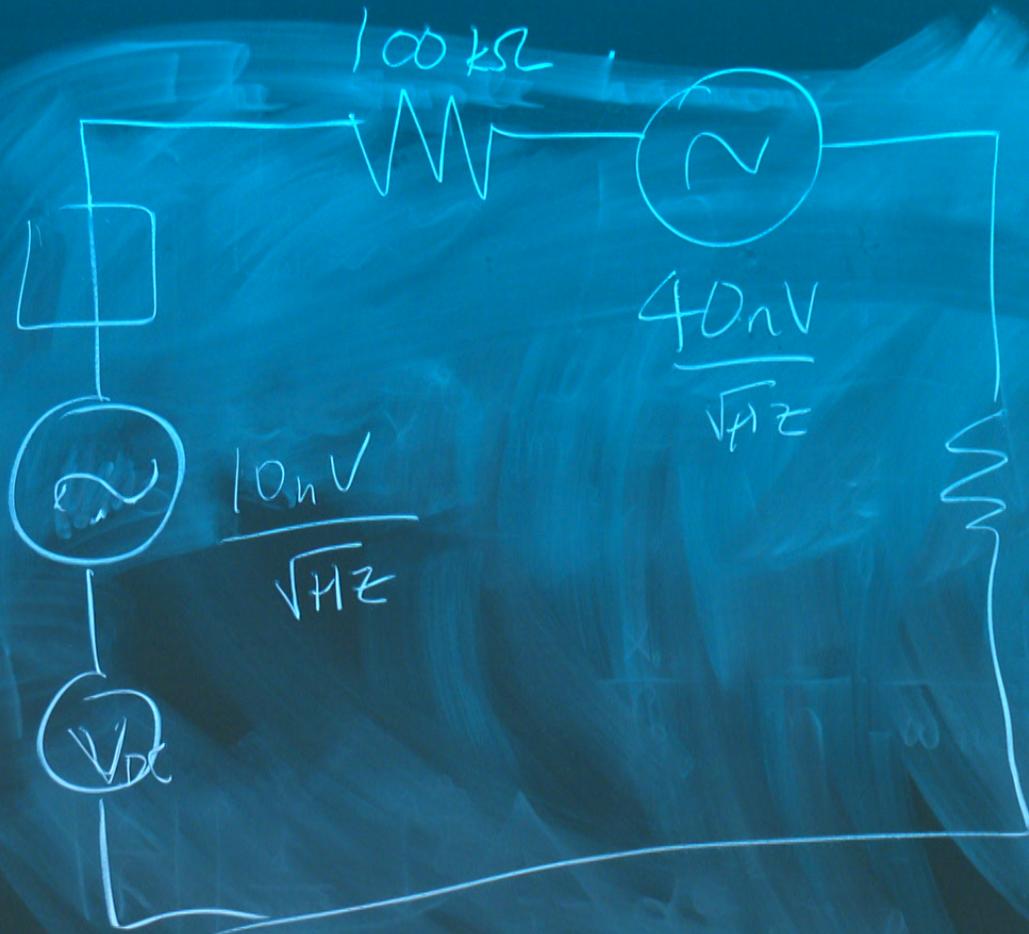

$$V_{\text{Resistor}}^2 = 4k_B T R \Delta f$$

for $100k\Omega$
 $\Rightarrow V_n \sim 40 \frac{nV}{\sqrt{Hz}}$

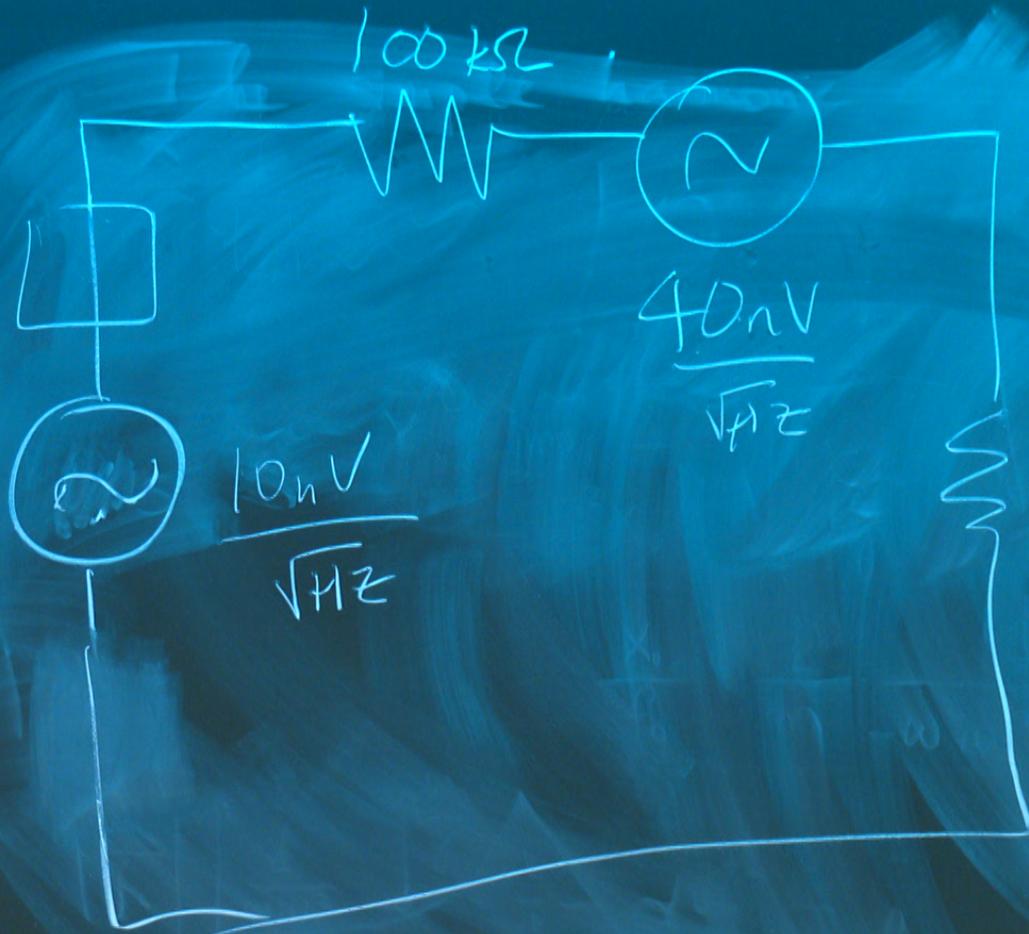

$50\Omega \rightsquigarrow 1\text{nV}$
 $\sqrt{1\text{Hz}}$

$$\sqrt{2} \text{ Resistor} = 4$$

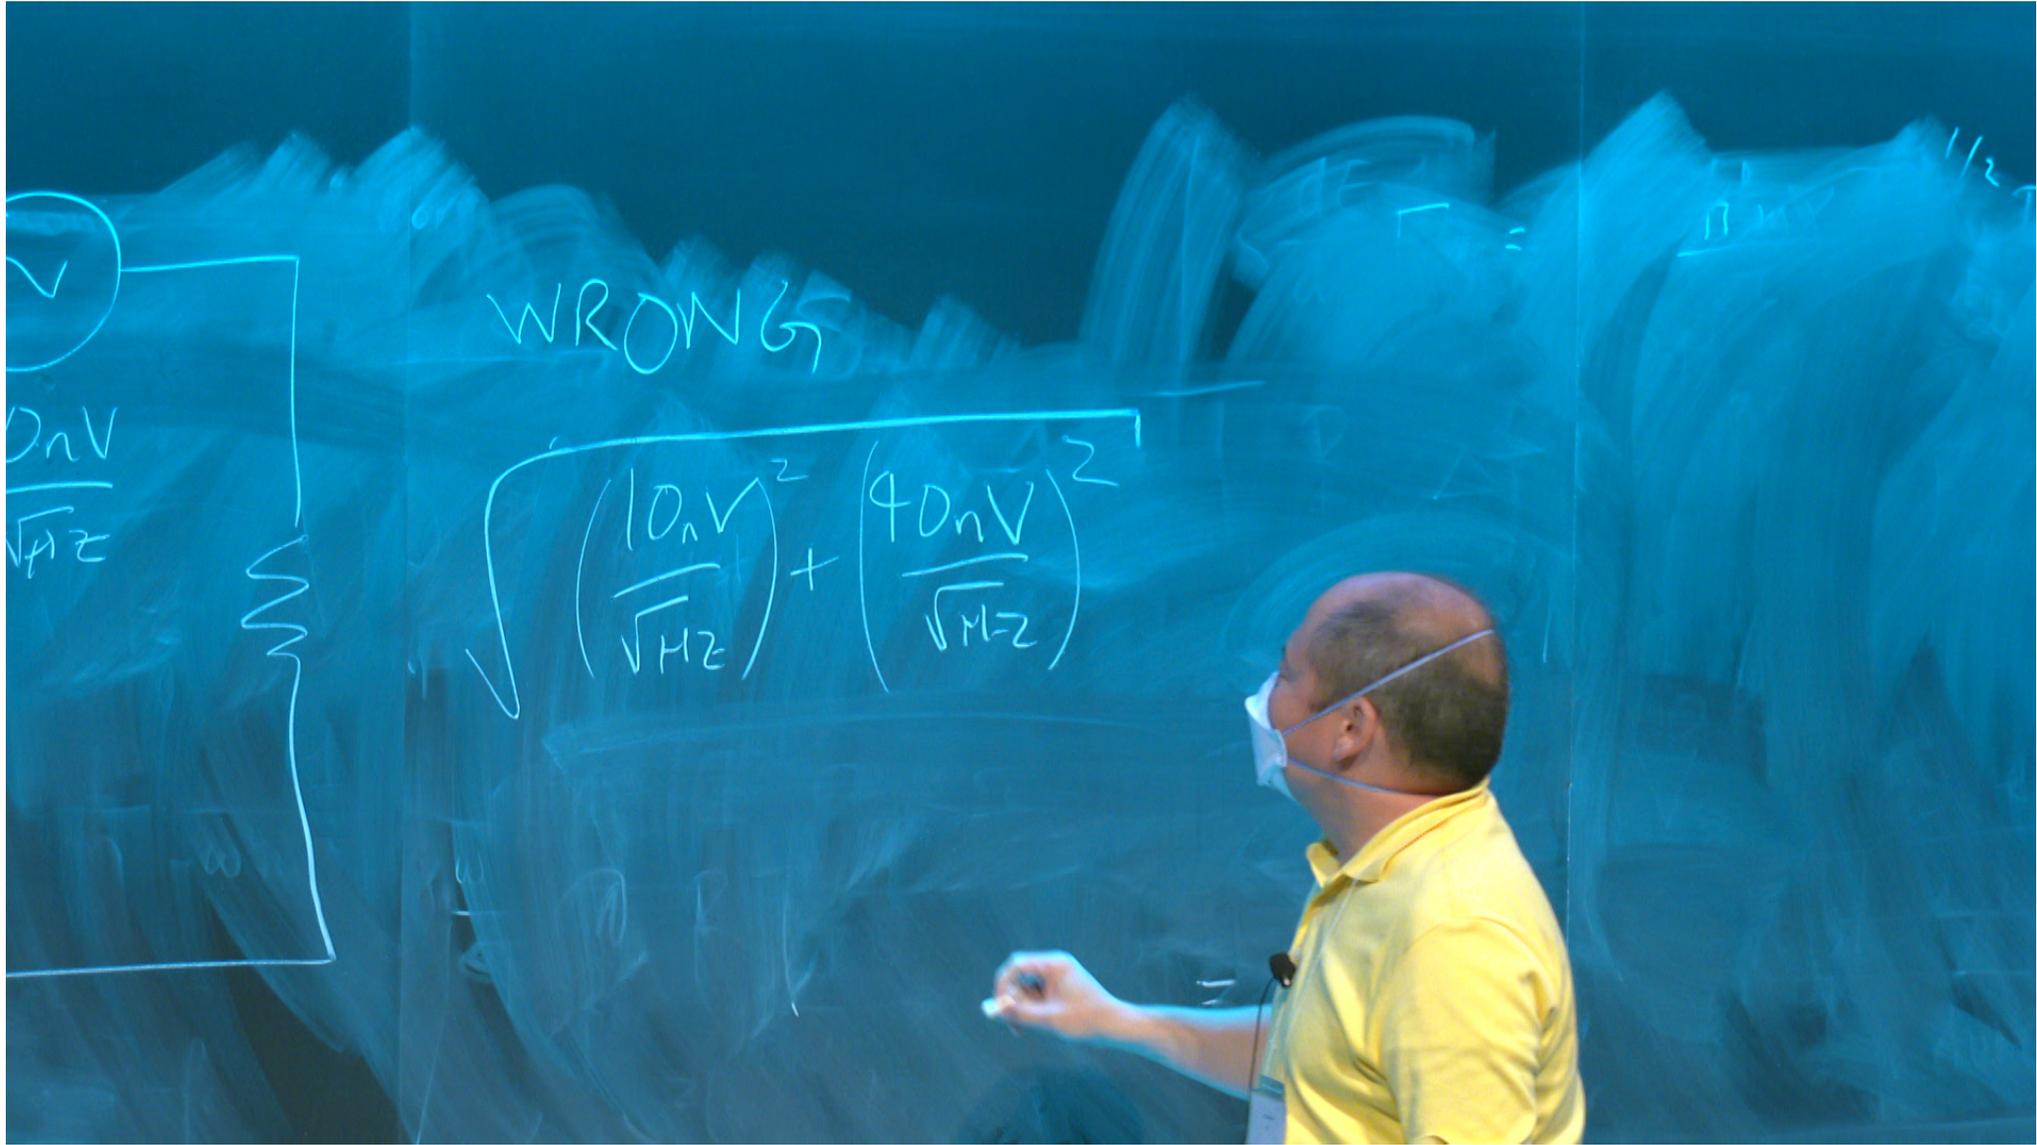

for 100kΩ
 → RT

WRONG

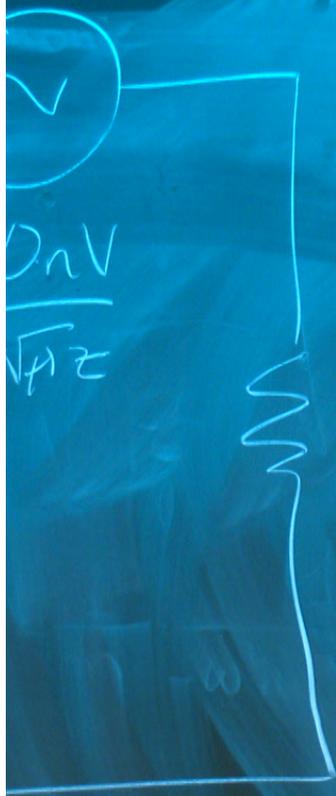

10 nV / √Hz

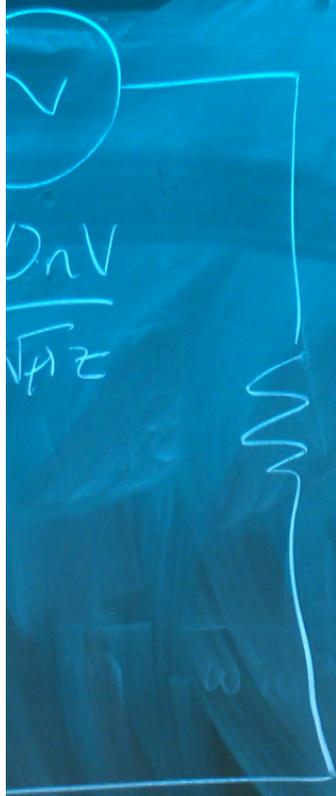

WRONG

$$\sqrt{\left(\frac{10\text{nV}}{\sqrt{\text{Hz}}}\right)^2 + \left(\frac{40\text{nV}}{\sqrt{\text{Hz}}}\right)^2}$$

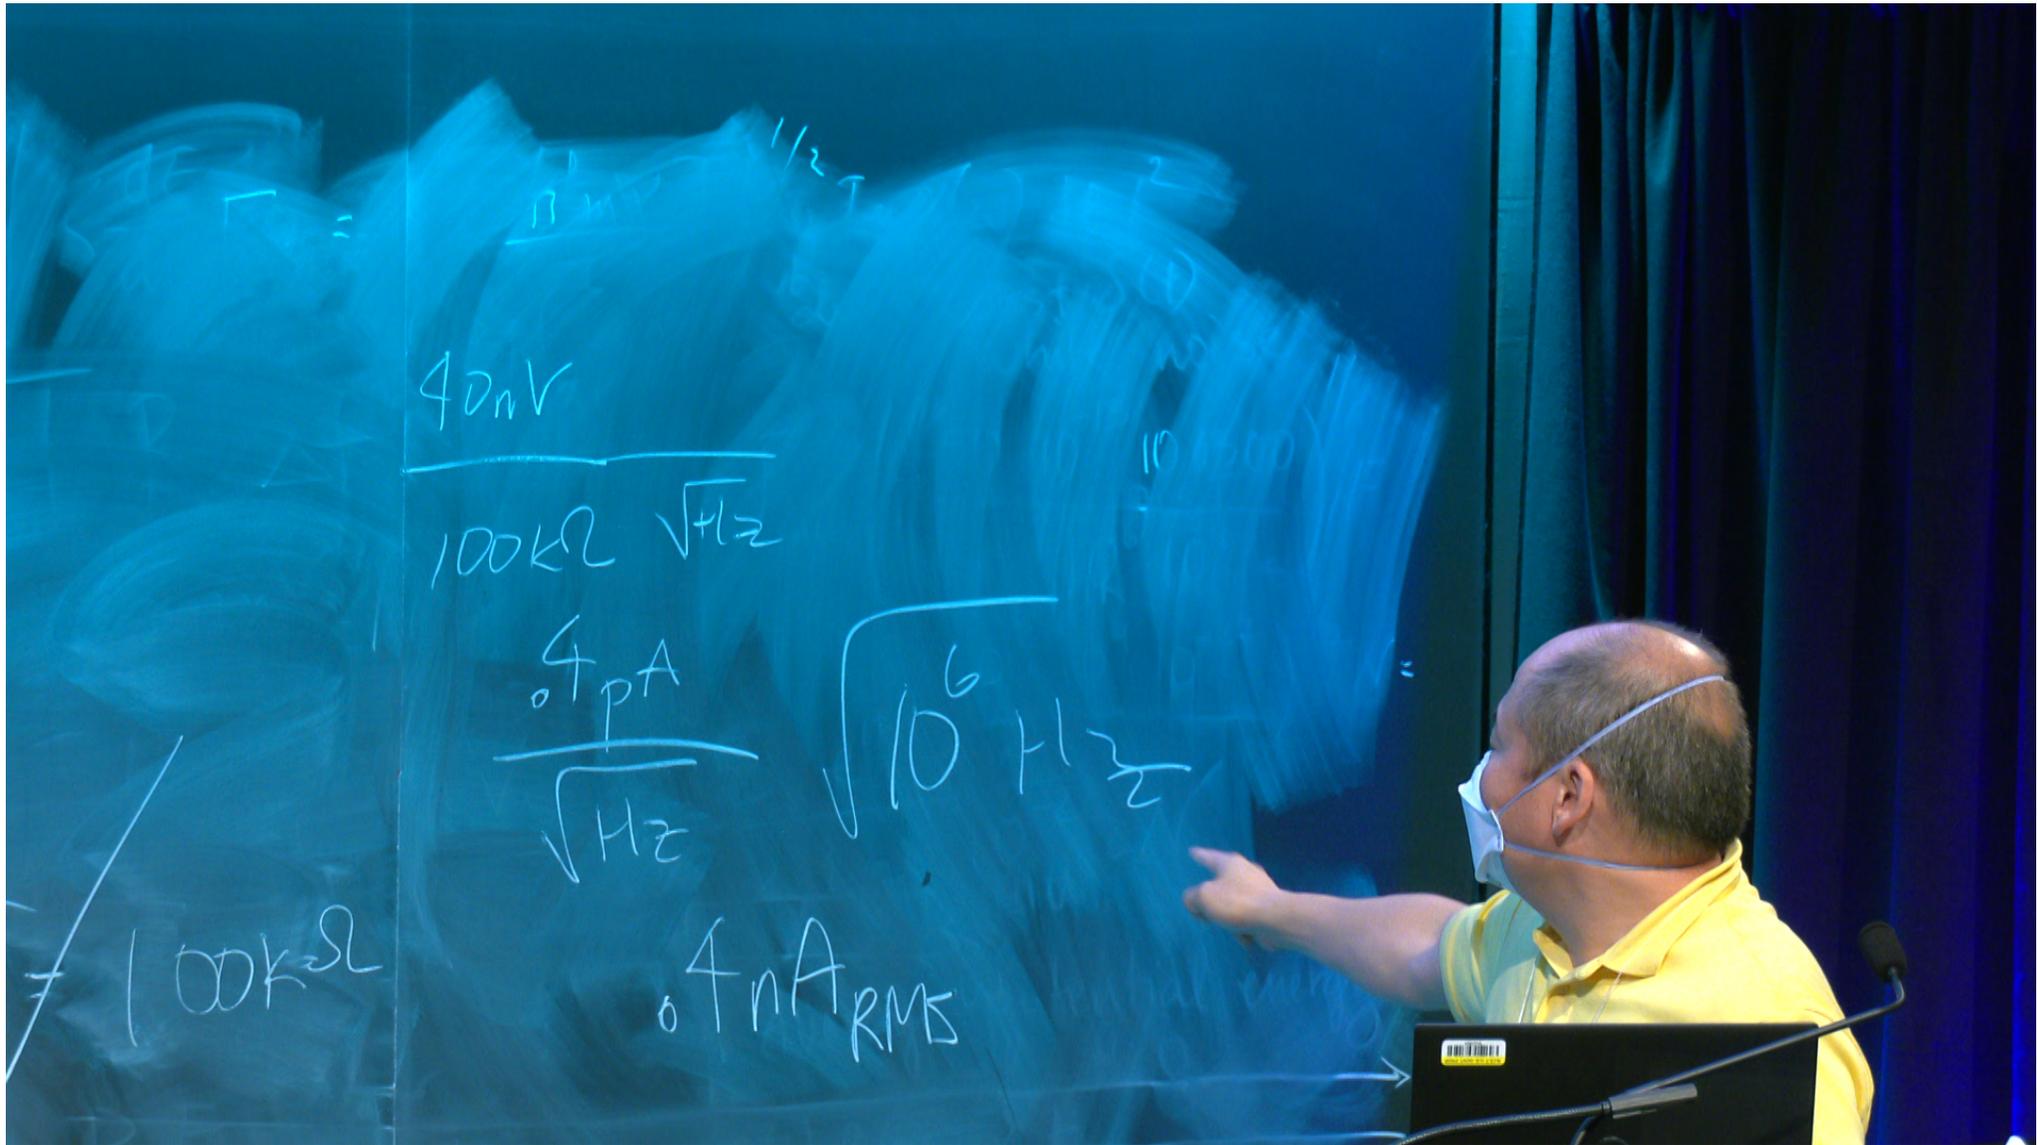

WRONG

$$\sqrt{\left(\frac{10\text{nV}}{\sqrt{\text{Hz}}}\right)^2 + \left(\frac{40\text{nV}}{\sqrt{\text{Hz}}}\right)^2}$$

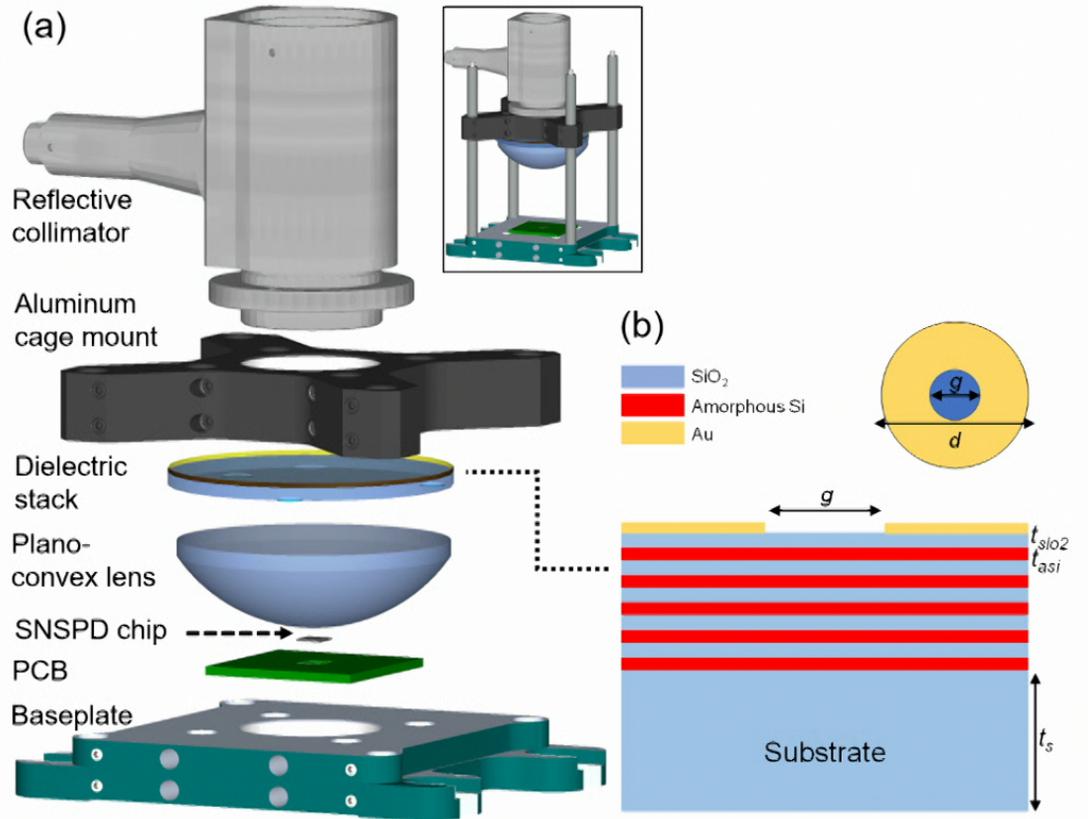

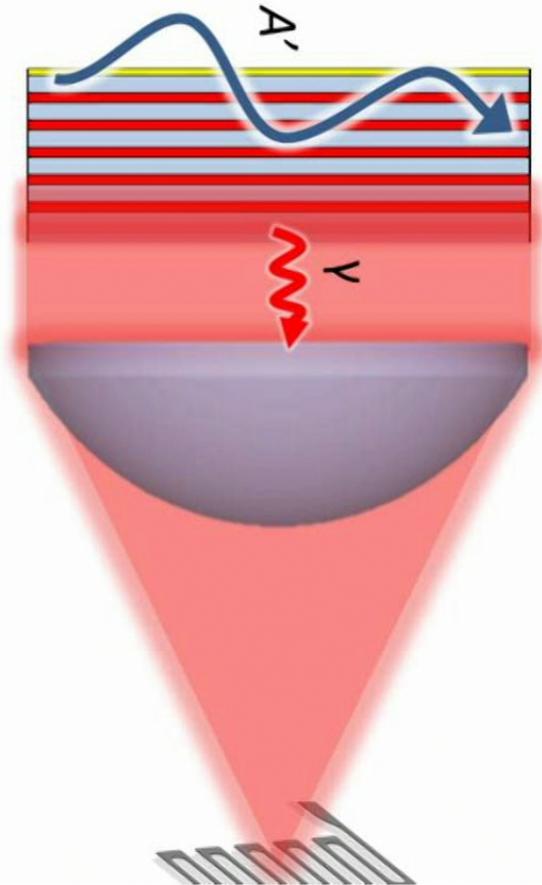

$$\frac{\sqrt{17} \times 10\text{nV}}{\sqrt{\text{Hz}}} \neq 100\text{k}\Omega$$

$$\frac{40\text{nV}}{100\text{k}\Omega \sqrt{\text{Hz}}}$$

$$\frac{4\text{pA}}{\sqrt{\text{Hz}}}$$

Optics

Comments about Noise

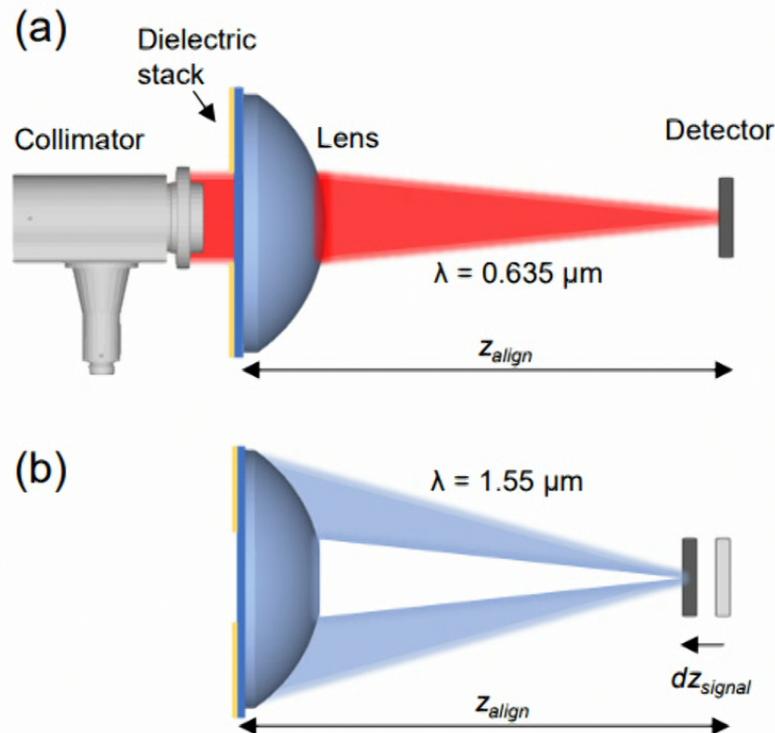

- Noise is unpredictable in amplitude and phase
- “60Hz” pickup... => not “random noise”
- Random noise:
 - Quantify by looking at the $\langle \text{noise}^2 \rangle$ because $\langle \text{noise} \rangle = 0$

$$\langle n^2 \rangle = \frac{1}{T} \int_0^T n(t)^2 dt$$

- Parseval’s Theorem:

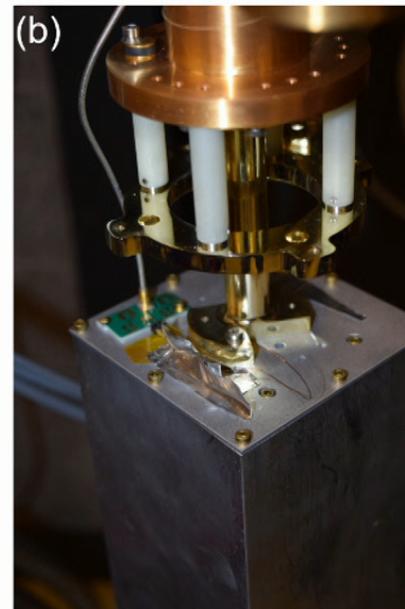

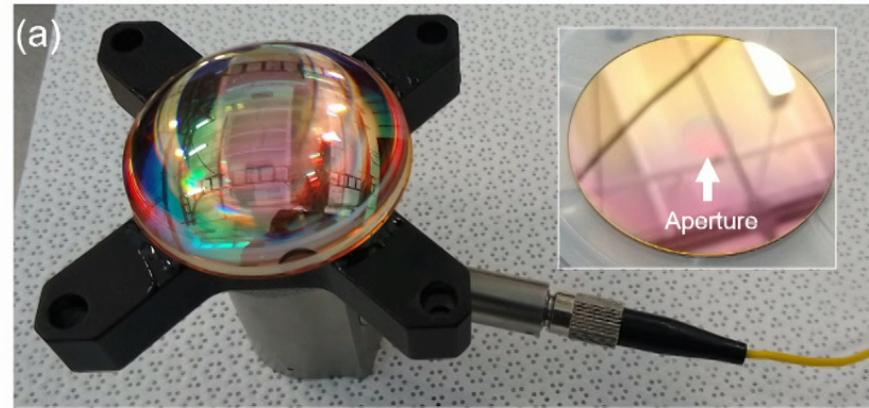

$$\langle n^2 \rangle = \frac{1}{T} \int_0^T n(t)^2 dt = \int \|\mathcal{N}(f)\|^2 df$$

How do align the lens to the device?

- Hole in Au mirror lets us put in a collimated red laser beam.
- Unfortunately focus for the red beam is not the same as for light from 1550 nm.
- Adjusted the distance after focusing with the red laser beam.
- Did not explicitly design the mechanics to account for thermal contraction... large uncertainty in collection efficiency

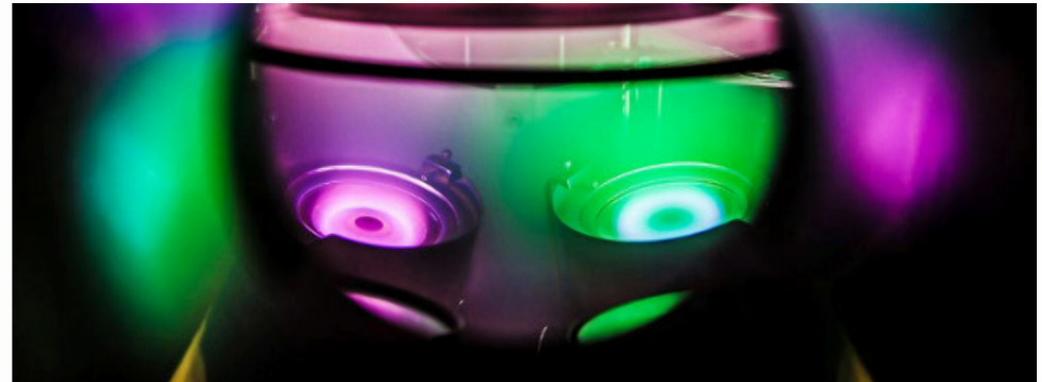

Light tight box...

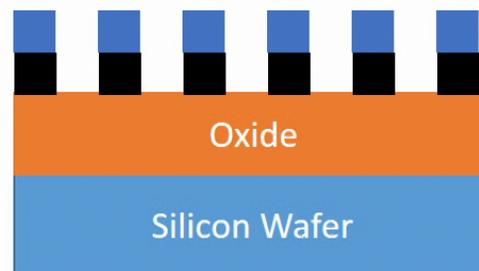

Detector Fabrication

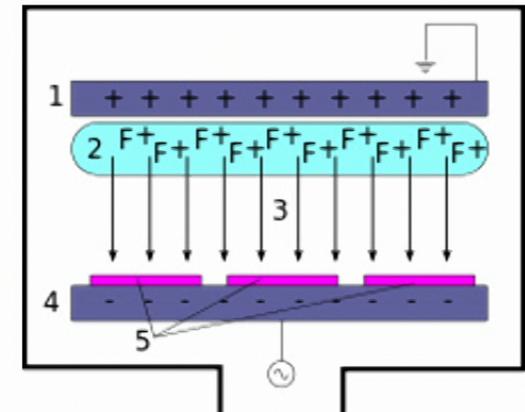

Sputter WSi

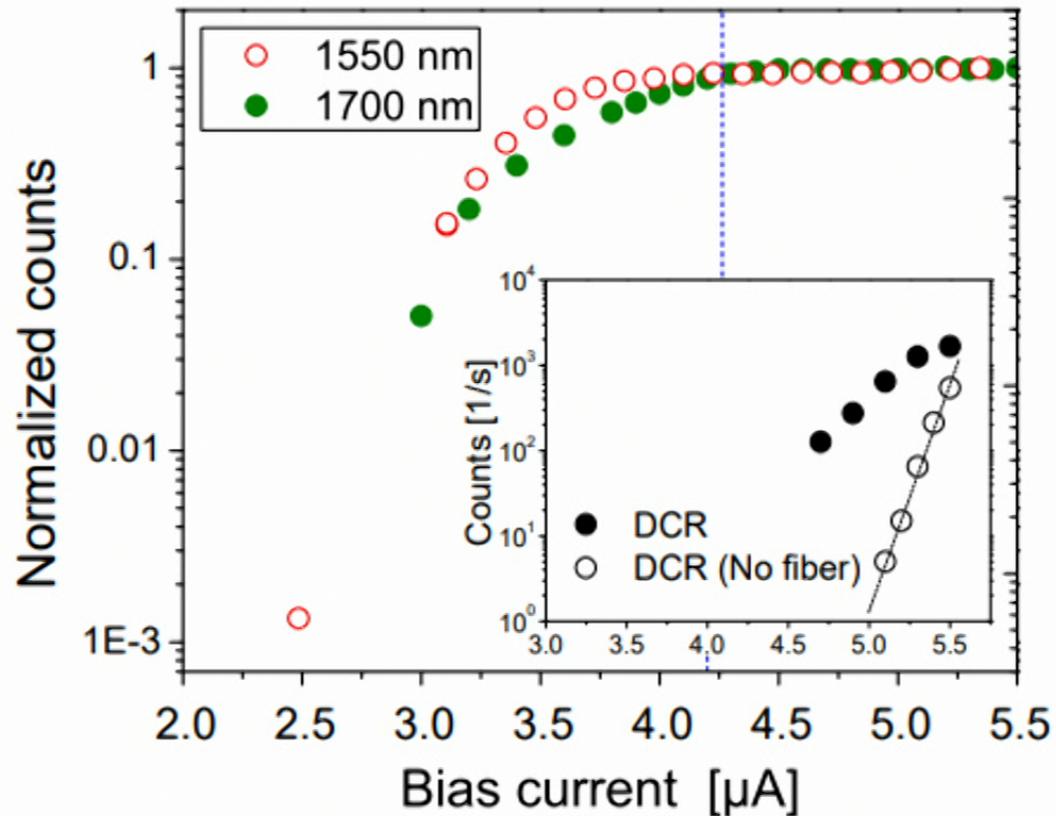

Coat and pattern e-beam resist

Etch WSi

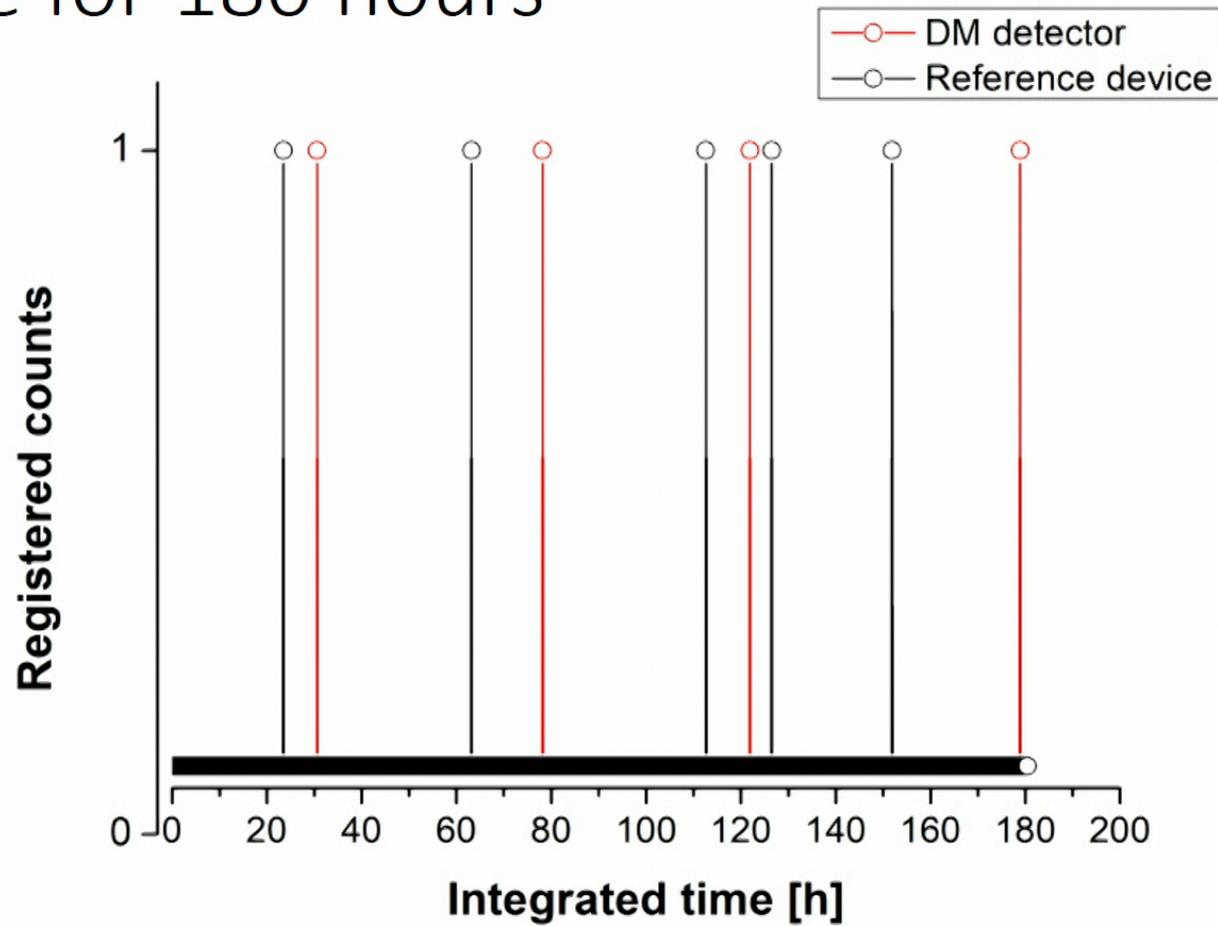

Picking the bias point / Calibration

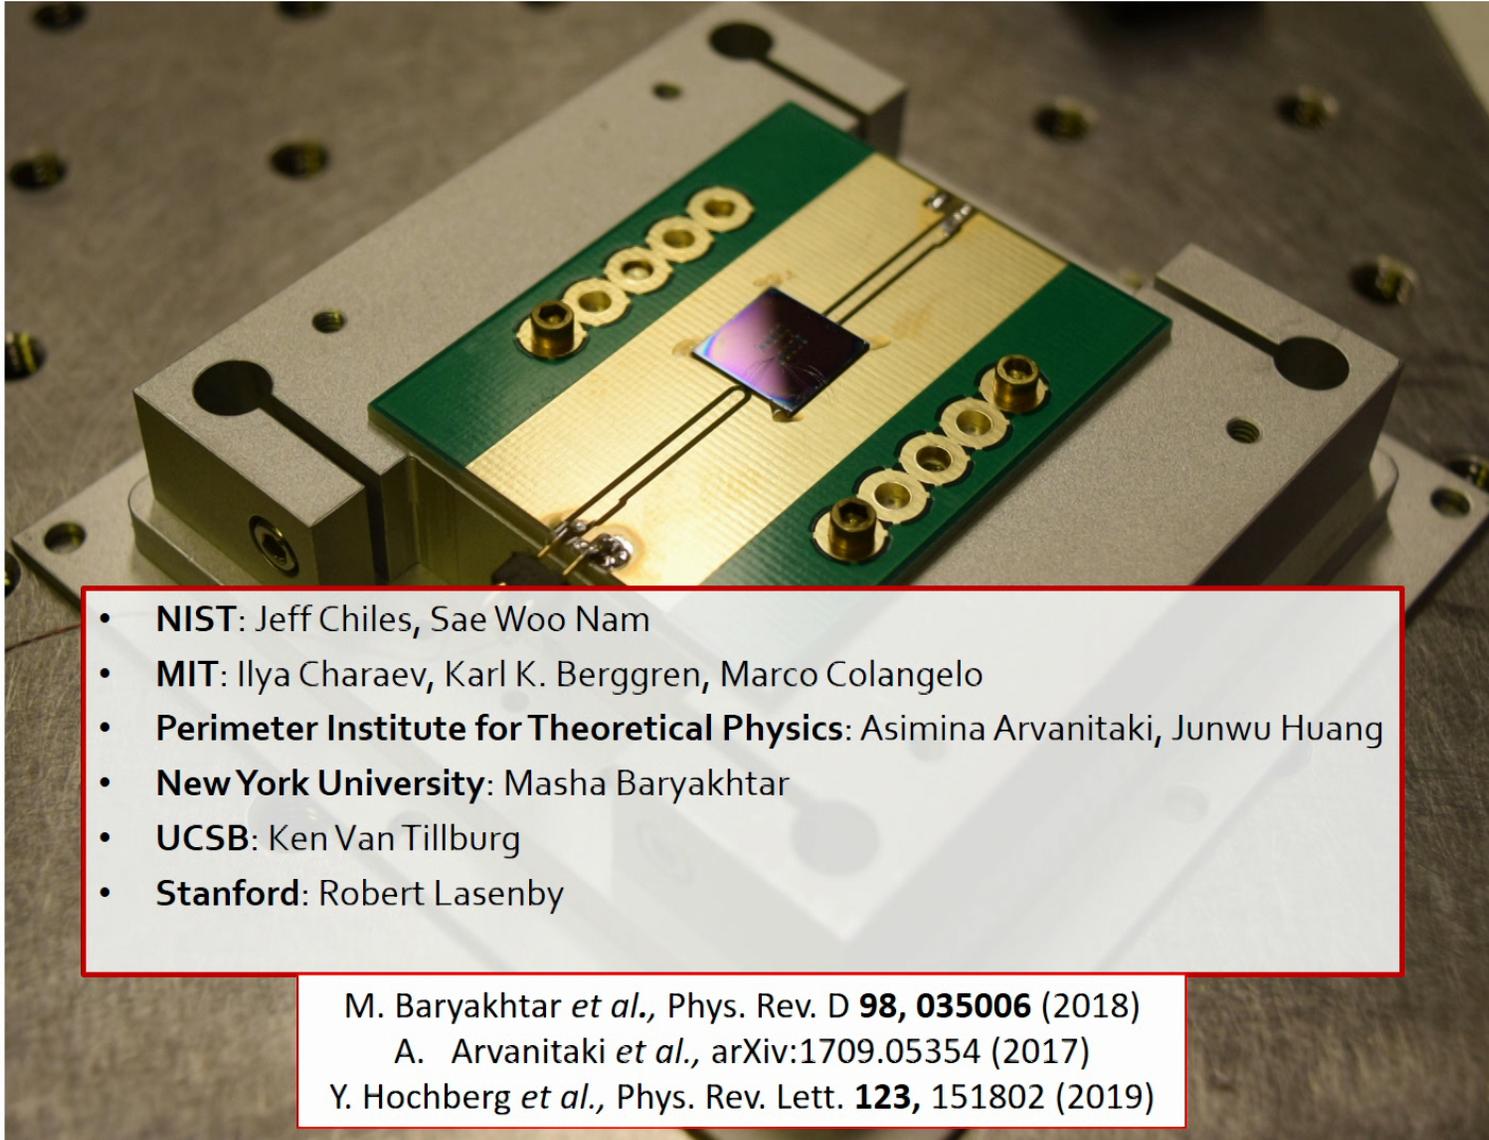

Two different laser colors to get an estimate of the difference in efficiency as a function of wavelength

So that exponentially disappearing dark counts will not occur at 1 count per day

Observe for 180 hours

What's next

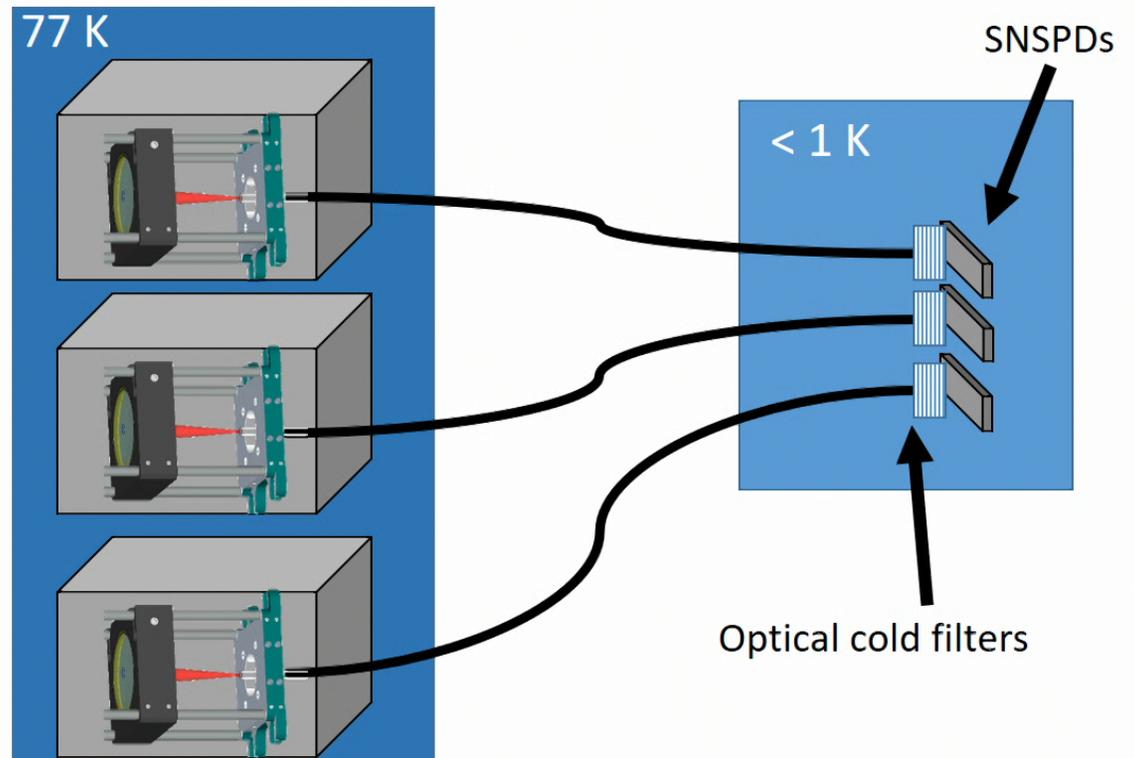

- Are the observed events an unwanted background signal
 - Muon veto
 - Local muon veto using a scintillator with SNSPD patterned on top
- Other mediators
- Axion
- Scaling up

Other Dark Matter Targets, Gas + Dielectrics:

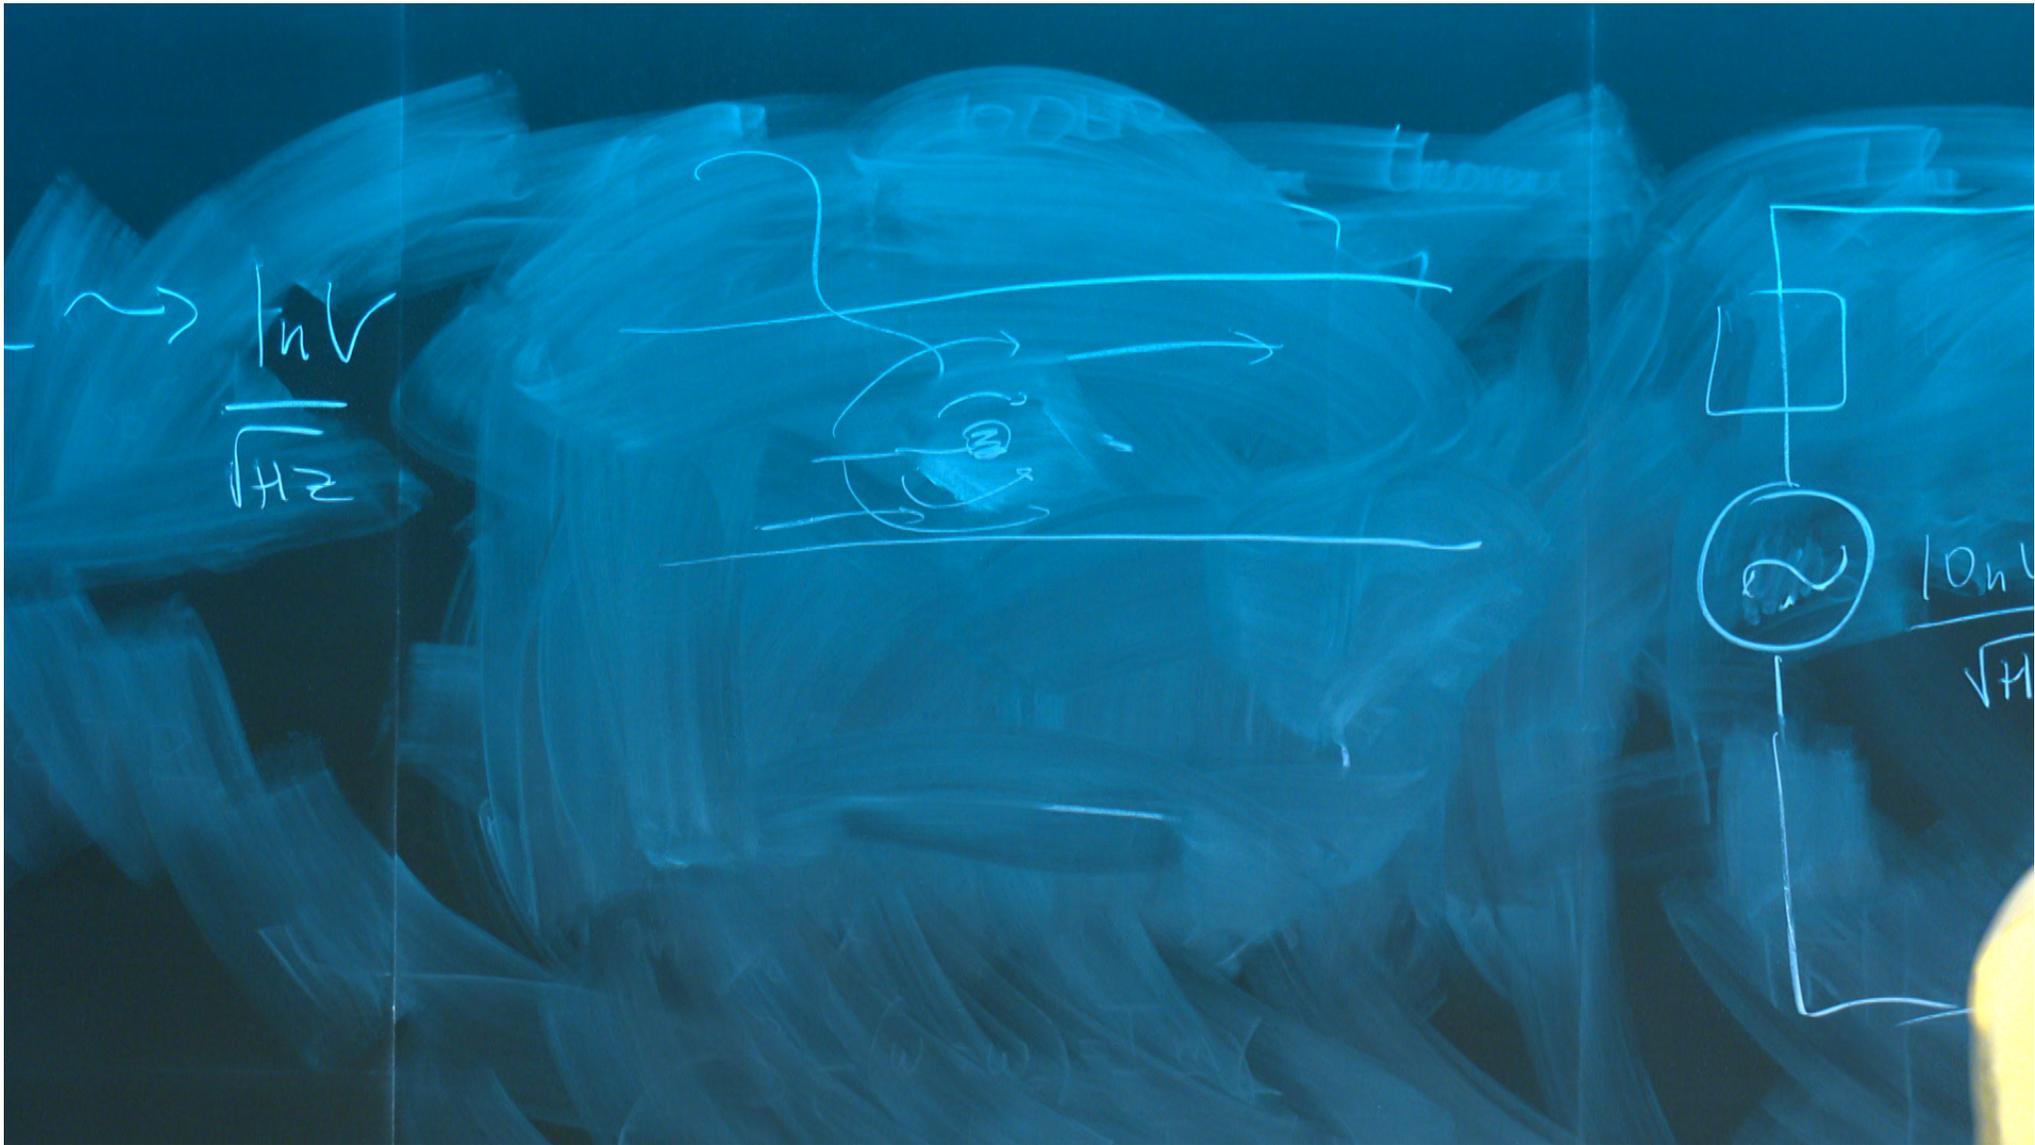

Future work: Axions, scaling to larger coverage

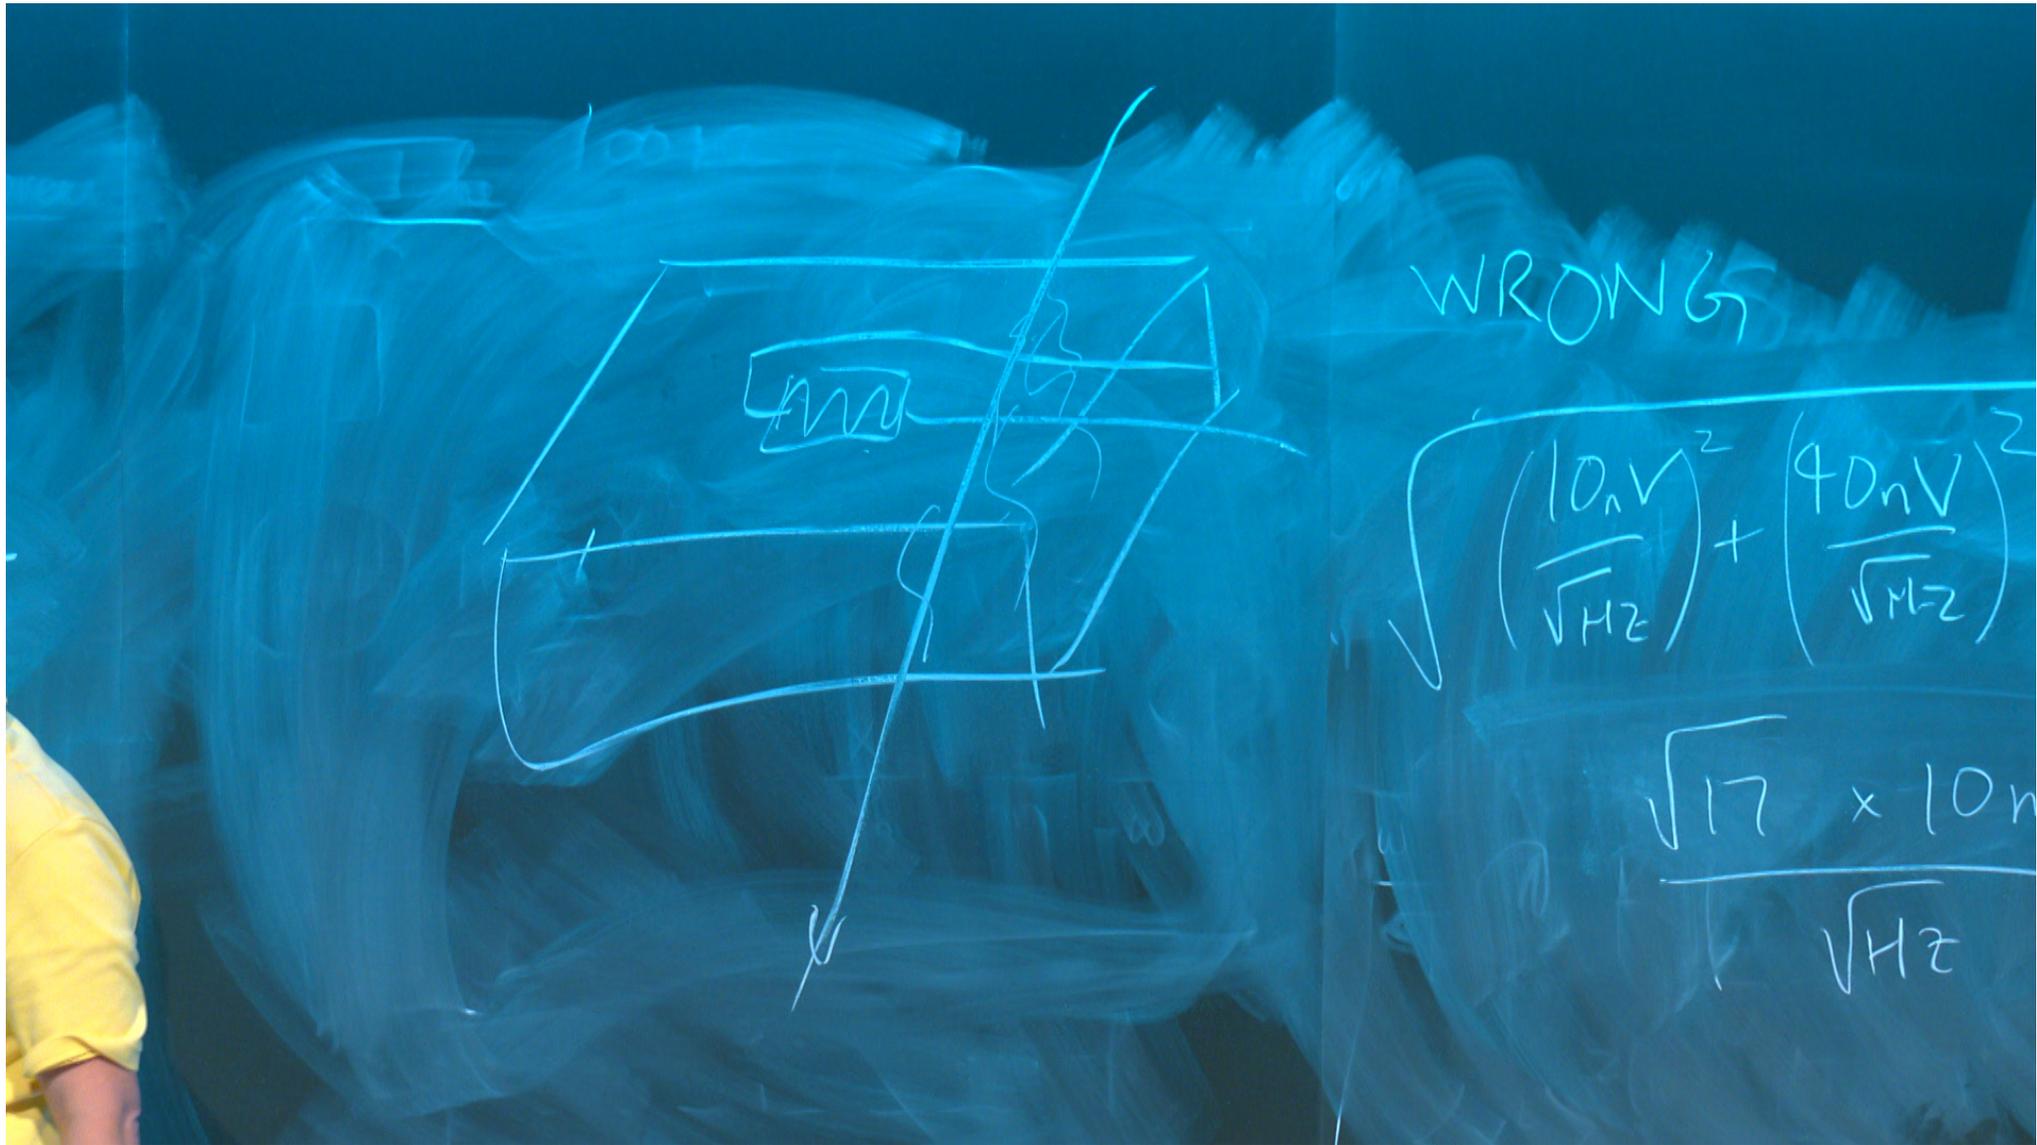

- Separate Dark Matter target from detectors
 - Could add B-field to detect Axions

Closing thoughts

- Superconducting devices / amplifiers enable detection of single photons from mm-waves to UV photons.
- Cryogenics has improved significantly in the last ten years.... It is slowly becoming “invisible”
- The ultimate performance of superconducting based single photon detectors is an open area of research.

WRONG

$$\sqrt{\left(\frac{10\text{nV}}{\sqrt{\text{Hz}}}\right)^2 + \left(\frac{40\text{nV}}{\sqrt{\text{Hz}}}\right)^2}$$

$$\frac{\sqrt{17} \times 10\text{nV}}{\sqrt{\text{Hz}}}$$

≠ 100k
