

Title: Machine Learning Lecture - 230309

Speakers: Lauren Hayward

Collection: Machine Learning for Many-Body Physics (2022/2023)

Date: March 09, 2023 - 9:00 AM

URL: <https://pirsa.org/23030031>

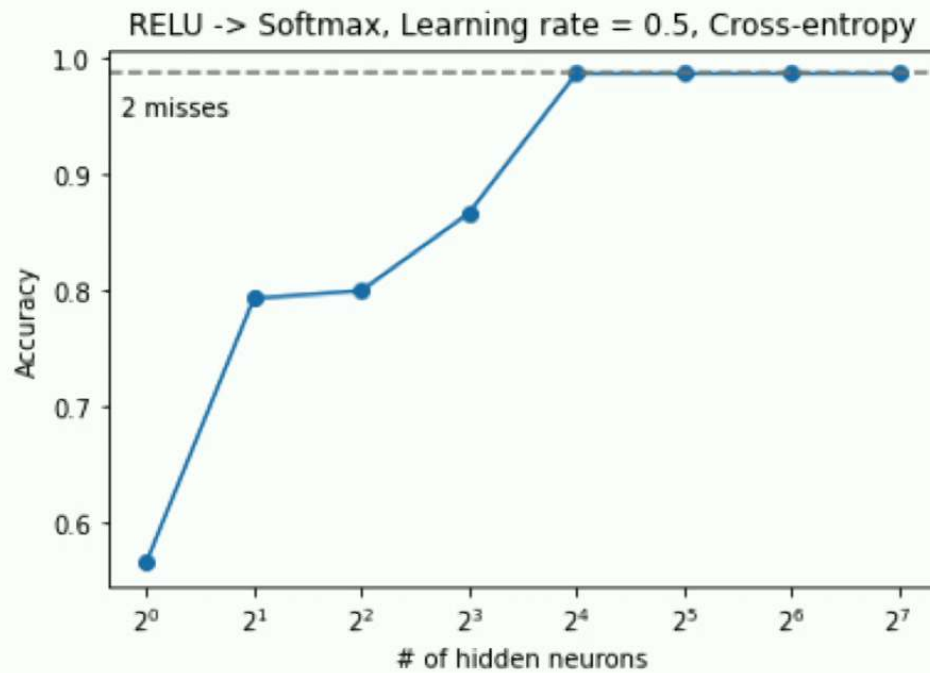

# Machine Learning for Many-Body Physics

## Lecture 6

## Tutorial 2, Problem 2

Accuracy vs. the number of neurons in the hidden layer

# Tutorial 2, Problem 2

Results from  
2022 students

## Accuracy vs. the magnitude of noise in the data

- learning\_rate = 0.1
- cost\_func = torch.nn.MSELoss()
- activation\_function = sigmoid
- number\_of\_layer and neurons: 1, 4
- N\_epochs = 100000

# Tutorial 2, Problem 2

Results from  
2022 students

Varying the  
number of  
different labels  
(branches)

# Tutorial 2, Problem 2

Results from  
2022 students

## Accuracy vs. the number of different labels (branches)

- learning rate = 1
- 4 neurons in the hidden layer
- first layer uses sigmoid
- outer layer uses softmax

# Tutorial 2, Problem 2

## Group 3

- 4 layers with 2, 20, 40, and k neurons
- Adam optimization wasn't working!
- Sigmoid activation function
- MSELoss

# Tutorial 2, Problem 2

## Group 3

- 4 layers with 2, 20, 40, and k neurons
- Adam optimization wasn't working!
- Sigmoid activation function
- MSELoss

# Tutorial 2, Problem 2

## Group 3

- 4 layers with 2, 20, 40, and k neurons
- Adam optimization wasn't working!
- Sigmoid activation function
- MSELoss

# Tutorial 2, Problem 2

## Group 3

- 4 layers with 2, 20, 40, and k neurons
- Adam optimization wasn't working!
- Sigmoid activation function
- MSELoss

# Tutorial 2, Problem 2

## Group 3

- 4 layers with 2, 20, 40, and k neurons
- Adam optimization wasn't working!
- Sigmoid activation function
- MSELoss

# Tutorial 2, Problem 2

## Group 3

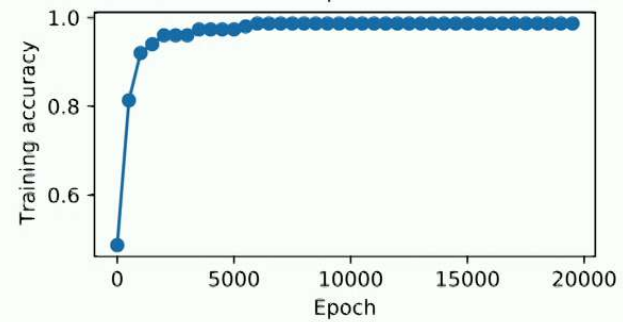

- 4 layers with 2, 20, 40, and k neurons
- Adam optimization wasn't working!
- Sigmoid activation function
- MSELoss

# Overfitting

Results from  
2022 students

```
mag_noise = 0.5  
hidden_size = 100

Random state

Ordered state

## Outline for today:

- Using supervised neural networks (NNs) to learn about phases of matter
  - ↳ Ising  $\mathbb{Z}_2$  gauge theory
- Recap of hyperparams. in NNs
- Monte Carlo sampling

Distinguishing phases of the classical Ising  $\mathbb{Z}_2$  gauge theory

$$H = -J \sum_P \left( \prod_{i \in P} s_i \right) \quad \text{with } s_i = +1 \text{ or } -1$$

The d.o.f. are on the bonds of the lattice

On a torus:

with  
periodic  
BC

$$s_i = +1 \text{ or } -1$$

$$\left( \begin{array}{c} | \\ \bullet \\ | \end{array} \text{ or } \begin{array}{c} | \\ | \end{array} \right)$$

Consider on plaquette  $p$

$$\prod_{i \in p} S_i = S_k S_l S_m S_n$$

At low  $T$ , there are 8 energetically-favoured plaquettes:

And 8 "excited" plaquettes:

There is topological order exactly at  $T=0$  in the thermodynamic limit and no order for  $T>0$

We can use the topological Wilson loop  $W_C$  as a measure of this order

$$W_C = \prod_{l \in C} S_l = \pm 1$$

In the topologically-ordered groundstate,  $W_{C_x}$  and  $W_{C_y}$  are constant for all choices of  $C_x$  and  $C_y$

Four possibilities:

$W_{C_x}$	$W_{C_y}$
+1	+1
+1	-1
-1	+1
-1	-1

are 8 energetically-favoured plaquettes:

plaquettes:

## Hyperparams for feedforward NNs

- # of layers (how "deep" the NN is)
- # of neurons in each hidden layer
- learning rate value, whether it decays with time
- activation function
- cost func.
- training algorithm (GD, SGD, Adam, ...)
- hyperparams. within training alg.: momentum  $\gamma$ , mini-batch size  $|B|$ , learning rate

- how much regularization is added to the cost (param.  $\lambda$ ) and what kind (L1, L2, ...)
- masking prob. if using dropout
- how we partition into training, validation, testing
- whether or not we add noise to our data, what kind and how much
- how the weights and biases are initialized
- 
- 
-

## Monte Carlo (MC) Sampling (Reference: Newman & Barkema)

(Used to generate data samples for HW1)

Consider a classical system where we want to calculate expectation values of quantities  $Q$

$$\langle Q \rangle = \sum_{\mu} Q_{\mu} P_{\mu}$$

For Boltzmann dist.:

$$P_{\mu} = \frac{1}{Z} e^{-\beta E_{\mu}}, \quad Z = \sum_{\mu} e^{-\beta E_{\mu}}$$

•  $E_\mu$  is the energy of config  $\mu$

•  $\beta = \frac{1}{k_B T}$

The sums  $\sum_\mu$  are over huge # of terms

( $2^N$  terms for classical Ising). Analytically intractable

Idea of MC: estimate  $\langle Q \rangle$  from  $M$

States  $\{\mu_1, \mu_2, \dots, \mu_M\}$ ,  $M \ll 2^N$

In particular, if each state  $\mu_i$  is selected from the set of all states according to the desired dist.  $p_{\mu_i}$ , then

$$\langle Q \rangle \approx Q_M = \frac{1}{M} \sum_{i=1}^M Q_{\mu_i} \quad \left( \begin{array}{l} \text{makes use of} \\ \text{"importance sampling"} \end{array} \right)$$

To implement this sampling, we can use  
Markov chain MC (MCMC)

↳ use the current state  $\mu$  to propose a move  
new related state  $\nu$ , and then decide to  
accept or reject proposal

eg) single spin flip

Ising  
model

propose  
→

Ising gauge theory:

propose  
→

In principle, any proposal is allowed

The prob. of moving from  $\mu$  to  $\nu$  is the transition prob.  $T(\mu \rightarrow \nu)$ , with  $\sum_{\nu} T(\mu \rightarrow \nu) = 1$

We can choose any set of transition probs.  $\{T(\mu \rightarrow \nu)\}$   
as long as we satisfy two conditions:

① Ergodicity: there is a non-zero prob. of  
transitioning (eventually) from  $\mu$  to  $\nu$

$$\mu \rightarrow \dots \rightarrow \nu$$

② Detailed balance (DB)

For the Boltzmann dist. :

$$\frac{T(\mu \rightarrow \nu)}{T(\nu \rightarrow \mu)} = e^{-\beta(E_\nu - E_\mu)}$$
